

Chapter 3

Linear Algebra

Here we discuss concepts in linear algebra - notably the literature on this subject is divided into two different schools. One introduces linear algebra as the mathematics and computation of multiply defined linear equations. Here the focus is on teaching linear algebra as a tool for manipulation and computation in multi-dimensional spaces. Determinants are introduced early on, and focuses are on matrix operations. The second approach is to treat matrices as abstract objects, laying focus to the structure of linear operators and vector spaces. Determinants and matrices are only introduced later. Here we provide both - the first will focus on the linear algebraic manipulation of matrices on finite-dimensional, Euclidean spaces. The second treatment will focus on the underlying mathematics of the structure of linear operators and their properties, including the mathematics in infinite dimensional vector spaces and over complex fields. Some of these treatments and notes on Linear Algebra herein are adapted from the texts from Ma et al. [6], Axler [1] and Roman [10].

3.1 Computational Methods in the Euclidean Space

3.1.1 Linear Systems

Definition 2 (Linear Equation). *A linear equation is one in which for variables $\{x_1, \dots, x_n\}$, equation takes form*

$$\sum_{i=1}^n a_i x_i = b \tag{2}$$

where $a_i \in \mathbb{R}, i \in [n]$ and $b \in \mathbb{R}$.

Definition 3 (Zero Equation). *A zero equation is a linear equation (see Definition 2) where all $i \in [n], a_i = 0$ and $b = 0$. That is,*

$$0x_1 + 0x_2 + \dots + 0x_n = 0. \tag{3}$$

The variables $x_i, i \in [n]$ in Definition 2 are not known and it is our task to solve for the solutions to these. The number of variables defines the dimensionality of our problem setting. For instance, see that the equation $ax + by + cz = d$ specify variables in the three-dimensional space $(x, y, z) \in \mathbb{R}^3$. For instance, the linear equation $z = 0$ specifies an xy-plane inside the xyz-space.

Definition 4 (Solution and Solution Sets to a Linear Equation). A solution to a linear equation (see Definition 2) is a set of numbers $\{x_1 = s_1, x_2 = s_2, \dots, x_n = s_n\}$ that satisfies the linear equation $s.t.$

$$\sum_{i=1}^n a_i s_i = b. \quad (4)$$

The set of all such solutions is called a solution set to the equation. When the solution set is expressed by equations representing exactly the equations in the solution set, these set of expressions are known as the general solution.

For instance, in the xy -space, solutions to the equation $x + y = 1$ are points taking the form $(x, y) = (1-s, s)$ where $s \in \mathbb{R}$. In the xyz -space, the solutions to the same equation are points $(x, y, z) = (1-s, s, t)$ where $s, t \in \mathbb{R}$. The solution set form points on a plane. The solution set to the zero equation (see Definition 3) is the entire space \mathbb{R}^n corresponding to the number of dimensions in the linear equation. The solution set to $\sum_i^n 0x_i \neq 0$ is \emptyset .

Definition 5 (Linear System). A finite set of m equations in n variables x_1, \dots, x_n is called a linear system and may be represented

$$a_{i1}x_1 + a_{i2}x_2 + \dots + a_{in}x_n = b_i, \quad i \in [m] \quad (5)$$

where $a_{ij}, i \in [m], j \in [n] \in \mathbb{R}$.

Definition 6 (Zero System). A zero system is a linear system (see Definition 5) where all the constants $a_{ji}, b_j, i \in [n], j \in [m]$ are zero.

Definition 7 (Solution and Solution Sets to a Linear System). A solution to a linear system (see Definition 5) is a set of numbers $\{x_1 = s_1, x_2 = s_2, \dots, x_n = s_n\}$ that satisfies all linear equations (i.e)

$$\sum_{i=1}^n a_{ji} s_i = b_j, \quad j \in [m] \quad (6)$$

The set of all such solutions is called a solution set to the system. When the solution set is expressed by equations representing exactly the equations in the solution set, these set of expressions are known as the general solution.

Definition 8 (Consistency of Systems). A system of linear equations that has solution set $\neq \emptyset$ is said to be consistent. Otherwise it is inconsistent.

Every system of linear equations will either be consistent or inconsistent. Consistent systems have either a unique solution or infinitely many solutions.

Exercise 2. Show that a linear system $Ax = b$ has either no solution, only one solution or infinitely many.

Proof. If the linear system is not consistent then it must have no solution. Otherwise, it may have a unique solution, or more than one solution. Suppose there are two solutions $u \neq v$ and $Au = Av = b$. Then we may write

$$A(tu + (1-t)v) = tAu + (1-t)Av = tb + (1-t)b = tb + b - tb = b. \quad (7)$$

This is valid for all $t \in \mathbb{R}$, and so we have infinitely many solutions. \square

For example, a system of two linear equations in two-dimensional space each representing a line has infinite solutions if they are the same line, no solution if they are parallel but different lines, and exactly one solution otherwise.

Exercise 3. In the xyz -space, the two equations

$$a_1x + b_1y + c_1z = d_1, \quad (E_1) \quad (8)$$

$$a_2x + b_2y + c_2z = d_2, \quad (E_2) \quad (9)$$

where $\exists a_1, b_1, c_1 \neq 0 \wedge \exists a_2, b_2, c_2 \neq 0$ represents two planes. The solution to the system is the intersection between the two planes. Logicize that there is either no solution ($E_1 // E_2$) or infinite number of solutions ($(E_1 = E_2) \vee (E_1 \text{ intersects } E_2 \text{ on a line})$).

3.1.1.1 Elementary Row Operations (EROs)

Definition 9 (Augmented Matrix Representation of Linear Systems). See that the system of linear equations (Definition 5) given

$$\forall j \in m, \quad \sum_{i=1}^n a_{ji}x_i = b_j \quad (10)$$

may be represented by the rectangular array of numbers

$$\left[\begin{array}{cccc|c} a_{11} & a_{12} & \cdots & a_{1n} & b_1 \\ a_{21} & a_{22} & \cdots & a_{2n} & b_2 \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} & b_m \end{array} \right] \quad (11)$$

and we call this the augmented matrix of the system. We denote this $(A|b)$. Sometimes, we omit this representation and just assign a single letter, say M , to represent the entire matrix.

Definition 10 (Elementary Row Operations). When we solve for a linear system, we implicitly or explicitly perform the following operations; *i*) multiply equation by some non-zero $k \in \mathbb{R}$, *ii*) interchange two equations, *iii*) add a multiple of one equation to another. In the augmented matrix (see Definition 9), these operations correspond to multiplying a row by a non-zero constant, swapping two rows and adding a multiple of one row to another row respectively. These three operations are collectively known as the elementary row operations. We adopt the following notations

1. $kR_i \equiv$ multiply row i by k .
2. $R_i \leftrightarrow R_j \equiv$ swap rows i, j .
3. $R_j + kR_i \equiv$ add k times of row i to row j .

Definition 11 (Row Equivalent Matrices). Two matrices A, B are said to be row equivalent if one may be obtained by another from a series of EROs. We denote this by

$$A \stackrel{\mathcal{R}}{\equiv} B. \quad (12)$$

Theorem 4 (Solution Sets of Row Equivalent Augmented Matrix Represented Linear Systems). Two linear systems (Definition 5) with augmented matrix representations $(A|b), (C|d)$ have the same solution set if $(A|b) \stackrel{\mathcal{R}}{\equiv} (C|d)$.

Proof. See proof in Exercise 14 using block matrix notations. □

3.1.1.2 Row-Echelon Forms

Definition 12 (Leading Entry). *The first non-zero number in a row of the matrix is said to be the leading entry of the row.*

Definition 13 (Zero Row). *Let the row representing a zero equation (see Definition 3) be called the zero row.*

Definition 14 (Zero Column). *Let the column representing all zero coefficients in the representative linear system for some variable (see Definition 6) be called the zero column. That is, the column has all zeros.*

Definition 15 (Row-Echelon Form (REF)). *A matrix is said to be row-echelon if the following properties hold:*

1. *Zero rows (Definition 13) are grouped at the bottom of the matrix.*
2. *If any two successive rows are non-zero rows, then the higher row has a leading entry (Definition 12) occurring at a column that is to the left of the lower row.*

For matrix A , we denote its matrix REF as $REF(A)$.

Definition 16 (Pivot Points/Columns). *The leading entries (Definition 12) of row-echelon matrices (Definition 15) are called pivot points. The column of a row-echelon form containing a pivot point is called a pivot column, and is otherwise a non-pivot column.*

Definition 17 (Reduced Row-Echelon Form (RREF)). *A reduced row-echelon-form matrix is a row-echelon-form matrix that has*

1. *All leading entries of non-zero row equal to one. (Definitions 12 and 13)*
2. *In each pivot column, all entries other than the pivot point is equal to zero. (Definition 16)*

For matrix A , we denote its matrix RREF as $RREF(A)$.

Note that a zero system is an REF (and also an RREF) by the Definitions 15 and 17. We show that obtaining the REF and RREF gives us an easy way to obtain the solution set to a linear system.

Exercise 4 (Finding solutions to REF, RREF Representations of Linear Systems; Back-Substitution Method). *Find the solution set to the linear systems represented by the following augmented matrices. (see Definitions 9, 5 and 4)*

- 1.

$$\left[\begin{array}{ccc|c} 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 2 \\ 0 & 0 & 1 & 3 \end{array} \right] \quad (13)$$

- 2.

$$\left[\begin{array}{ccccc|c} 0 & 2 & 2 & 1 & -2 & 2 \\ 0 & 0 & 1 & 1 & 1 & 3 \\ 0 & 0 & 0 & 0 & 2 & 4 \end{array} \right] \quad (14)$$

3.

$$\left[\begin{array}{cccc|c} 1 & -1 & 0 & 3 & -2 \\ 0 & 0 & 1 & 2 & 5 \\ 0 & 0 & 0 & 0 & 0 \end{array} \right] \quad (15)$$

4.

$$\left[\begin{array}{ccc|c} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{array} \right] \quad (16)$$

5.

$$\left[\begin{array}{cc|c} 3 & 1 & 4 \\ 0 & 2 & 1 \\ 0 & 0 & 1 \end{array} \right] \quad (17)$$

Proof. 1. It is easy to see that $x_1 = 1, x_2 = 2, x_3 = 3$ is the unique solution this linear system.

2. Since this represents the linear system

$$2x_2 + 2x_3 + x_4 - 2x_5 = 2, \quad (18)$$

$$x_3 + x_4 + x_5 = 3, \quad (19)$$

$$2x_5 = 4, \quad (20)$$

solve. We let the solutions to variables of non-pivot columns be arbitrary. That is, $x_1 \in \mathbb{R}$. The third equation says $x_5 = 2$. Substituting into the second equation, get

$$x_3 + x_4 + 2 = 3, \quad (21)$$

so $x_3 = 1 - x_4$. Substituting into first equation,

$$2x_2 + 2(1 - x_4) + x_4 - 2 \cdot 2 = 2, \quad (22)$$

so $x_2 = 2 + \frac{1}{2}x_4$. So there are two free parameters, and we arrive at the general solution $(x_1, x_2, x_3, x_4, x_5) = (s, 2 + \frac{1}{2}t, 1 - t, t, 2)$, where $s, t \in \mathbb{R}$. This technique is known as the back-substitution method.

3. By the same back-substitution method, arrive at the general solution $(x_1, x_2, x_3, x_4) = (-2 + s - 3t, s, 5 - 2t, t)$ where $s, t \in \mathbb{R}$.

4. The solution set is $(r, s, t) = \mathbb{R}^3$.

5. This system is inconsistent! (Definition 8)

□

3.1.1.3 Gaussian Elimination Methods

Let $A \stackrel{\mathcal{R}}{\equiv} R$. If R is (R)REF, R is said to (reduced) row-echelon form of A and A is said to have (R)REF form R .

Theorem 5 (Gaussian Elimination/Row Reduction and Gauss-Jordan Elimination). *We outline the algorithm to reduce a matrix A to its REF B .*

1. Locate the leftmost non-zero column (see Definition 14).
2. If this happens to be the top-most column, then continue. Else, swap the top row with the row corresponding to the leading entry (Definition 12) found in the previous step.
3. For each row below the top row, add a suitable multiple so that all leading entries below the leading entry of the top row equals zero.
4. From the second row onwards, repeat algorithm from step 1 applied to the submatrix until REF is obtained.

To further get a RREF from REF obtained,

5. Multiply a suitable constant to each row so that all the leading entries become one.
6. From the bottom row onwards, add suitable multiples of each row such that all rows above the leading entries at pivot columns (Definition 16) are all zero.

Steps 1 – 4 are known as *Gaussian Elimination*. Obtaining the RREF via Steps 1 – 6 is known as *Gauss-Jordan elimination*.

Exercise 5. Obtain the RREF of the following augmented matrix

$$\left[\begin{array}{ccccc|c} 0 & 0 & 2 & 4 & 2 & 8 \\ 1 & 2 & 4 & 5 & 3 & -9 \\ -2 & -4 & -5 & -4 & 3 & 6 \end{array} \right] \quad (23)$$

via *Gauss-Jordan Elimination* (see Theorem 5).

Proof. Recall the notations for EROs (see Definition 10). We perform the following steps;

$$\left[\begin{array}{ccccc|c} 1 & 2 & 4 & 5 & 3 & -9 \\ 0 & 0 & 2 & 4 & 2 & 8 \\ -2 & -4 & -5 & -4 & 3 & 6 \end{array} \right] \quad R_1 \leftrightarrow R_2, \quad (24)$$

$$\left[\begin{array}{ccccc|c} 1 & 2 & 4 & 5 & 3 & -9 \\ 0 & 0 & 2 & 4 & 2 & 8 \\ 0 & 0 & 3 & 6 & 9 & -12 \end{array} \right] \quad R_3 + 2 \cdot R_1, \quad (25)$$

$$\left[\begin{array}{ccccc|c} 1 & 2 & 4 & 5 & 3 & -9 \\ 0 & 0 & 2 & 4 & 2 & 8 \\ 0 & 0 & 0 & 0 & 6 & -24 \end{array} \right] \quad R_3 - \frac{3}{2} \cdot R_2, \quad (26)$$

$$\left[\begin{array}{ccccc|c} 1 & 2 & 4 & 5 & 3 & -9 \\ 0 & 0 & 1 & 2 & 1 & 4 \\ 0 & 0 & 0 & 0 & 1 & -4 \end{array} \right] \quad \frac{1}{2}R_2, \quad \frac{1}{6}R_3, \quad (27)$$

$$\left[\begin{array}{ccccc|c} 1 & 2 & 4 & 5 & 0 & 3 \\ 0 & 0 & 1 & 2 & 0 & 8 \\ 0 & 0 & 0 & 0 & 1 & -4 \end{array} \right] \quad R_2 - 1 \cdot R_3, \quad R_1 - 3 \cdot R_3, \quad (28)$$

$$\left[\begin{array}{ccccc|c} 1 & 2 & 4 & -3 & 0 & -29 \\ 0 & 0 & 1 & 2 & 0 & 8 \\ 0 & 0 & 0 & 0 & 1 & -4 \end{array} \right] \quad R_1 - 4 \cdot R_2. \quad (29)$$

□

Result 2 (REF and their Interpretations for Solution Sets). *Consider the REF $(A|b)$ augmented matrix form (see Definition 9). Note that every matrix has a unique RREF but can have many different REFs. If a linear system is not consistent (Definition 8), then the last column of the REF form of the augmented matrix is a pivot column. In other words, there will be a row representing an equation where $\sum_i^n 0x_i = c$, but $c \neq 0$. There is no solution to this linear system. A consistent linear system has a unique solution if except the last column b , every column is a pivot column. This system has as many variables in the linear system as the number of nonzero rows in the REF. If there exists a non-pivot column in the REF that is not the last one (b), then this consistent linear system has infinitely many solutions. This linear system has number of variables greater than the number of non-zero rows in the REF.*

Note that when solving for linear systems in which the contents are unknown constants, then we need to be careful about performing illegal row operations. That is, assume an augmented matrix

$$\left[\begin{array}{ccc|c} a & 1 & 0 & a \\ 1 & 1 & 1 & 1 \\ 0 & 1 & a & b \end{array} \right] \quad (30)$$

and in order to make the second row leading entry 0, we would perhaps like to perform $R_2 - \frac{1}{a}R_1$. However, we do not know that $a \neq 0$. In this case, we can consider either first swapping the first and second row and progressing, or perform a by-case method.

3.1.1.4 Homogeneous Linear Systems

Definition 18 (Homogeneous Linear Systems). *A linear system (Definition 18) is homogeneous (HLS) if it has augmented matrix representation $(A|b)$ where $b = 0$ and all constants $a_{ij} \in \mathbb{R}, \forall i \in [m], \forall j \in [n]$.*

See that the HLS is always satisfied by $x_i = 0, i \in [n]$ and we call this the trivial (sometimes, zero) solution. A non-trivial solution is any other solution that is not trivial.

Exercise 6. *See that in the xy -plane, the equations*

$$a_1x + b_1y = 0, \quad (31)$$

$$a_2x + b_2y = 0 \quad (32)$$

where a_1, b_1 not both zero and a_2, b_2 not both zero each represent straight lines through the origin, The system has only the trivial solution when the two equations are not the same line, otherwise they have infinitely many solutions. In the xyz -space, a system of two such linear equations passing through the origin always has infinitely many (non-trivial) solutions in addition to the trivial one, since they are either the same plane or intersect at a line passing through the origin at $(0, 0, 0)$.

Lemma 2. *A HLS (Definition 18) has either only the trivial solution or infinitely many solutions in addition to the trivial solution. A HLS with more unknowns than equations has infinitely many solutions.*

Proof. The first assertion is trivial since the zero solution satisfies it. The second assertion follows from considering the REF of the augmented matrix representation of a HLS with more unknowns than equations, then apply Result 2. \square

Exercise 7. *For a HLS $Ax = 0$ (Definition 18) with non-zero solution, show that the system $Ax = b$ has either no solution or infinitely many solutions.*

Proof. By Theorem 2, a HLS system has no solution, one solution or infinite solutions. But suppose there is some solution u s.t. $Au = b$. Let v be non-zero solution for the HLS s.t. $Av = 0$, $v \neq 0$. Then $A(u+v) = Au + Av = b + 0 = b$, so $u+v$ is solution and $u+v \neq u$. But by Lemma 2, the solution space for $Ax = 0$ must have infinitely many vectors if such a v exists. It follows $Ax = b$ has infinitely many solutions if $\exists u$ s.t. $Au = b$. \square

3.1.2 Matrices

We formally defined augmented matrices in Definition 9. In the earlier theorems, we also referred to generalized matrix representations of numbers. We provide formal definition here.

Definition 19 (Matrix). *A matrix is a rectangular array (or array of arrays) of numbers. The numbers are called entries. The size of a matrix is given by the rectangle's sides, and we say a matrix A is $m \times n$ for m rows and n column matrix. We can denote the entry at the i -th row and j -th coordinate by writing $A_{(i,j)} = a_{ij}$. This is often represented*

$$A = \begin{bmatrix} a_{11} & a_{12} \cdots & a_{1n} \\ a_{21} & a_{22} \cdots & a_{2n} \\ \cdots & \cdots \cdots & \cdots \\ a_{m1} & a_{m2} \cdots & a_{mn} \end{bmatrix}, \quad (33)$$

and for brevity we also denote this $A = (a_{ij})_{m \times n}$, and sometimes we drop the size all together and write $A = (a_{ij})$.

Definition 20. *For brevity, given a matrix A (Definition 19) we refer to its size by using the notation $nrows(A)$ and $ncols(A)$ to indicate the number of rows in A and number of columns in A respectively. That is, A is a matrix size $nrows(A) \times ncols(A)$.*

Definition 21 (Column, Row Matrices/Vectors). *A column matrix (vector) is a matrix with only a single column. A row matrix (vector) is a matrix with only one row.*

Definition 22 (Square Matrix). *A square matrix is a matrix (Definition 19) that is square (number of rows is equivalent to the number of rows). We say $A_{n \times n}$ square matrix is of order n .*

Definition 23 (Diagonal Matrix). *A square matrix A of order n (Definition 22) is diagonal matrix if all entries that are not along the diagonal are zero. That is,*

$$a_{ij} = 0 \quad \text{when } i \neq j. \quad (34)$$

Definition 24 (Scalar Matrix). *A diagonal matrix (Definition 23) is scalar matrix if all diagonal entries are the same, that is*

$$a_{ij} = \begin{cases} 0 & i \neq j \\ c & i = j, \end{cases} \quad (35)$$

for some constant $c \in \mathbb{R}$.

Definition 25 (Identity Matrix). *Scalar matrix (Definition 24) is identity matrix if the diagonals are all one, that is $c = 1$. We often denote this as $\mathbb{1}$. If the size needs to be specified, we add subscript $\mathbb{1}_n$ to indicate order n .*

Definition 26 (Zero Matrix). *Arbitrary matrix $m \times n$ is zero matrix if all entries are zero.*

Definition 27 (Symmetric Matrix). *A square matrix A (Definition 22) is symmetric if $a_{ij} = a_{ji}$ for all $i, j \in [n]$.*

Definition 28 (Triangular Matrix). *A square matrix A (Definition 22) is upper triangular if $a_{ij} = 0$ whenever $i > j$, and is lower triangular if $a_{ij} = 0$ whenever $i < j$.*

3.1.2.1 Operations on Matrices

Definition 29 (Matrix Addition, Subtraction and Scalars). *The following are defined for operations on matrices:*

1. *Scalar Multiplication: $cA = (ca_{ij})$.*
2. *Matrix addition: $A + B = (a_{ij} + b_{ij})$.*
3. *Matrix subtraction: $A - B = (a_{ij} - b_{ij})$.¹ We denote $-A = -1 \cdot A$.*

Definition 30 (Matrix Equality). *To show that two matrices A, B are equal, we have to show their their size is the same, and their entries $a_{ij} = b_{ij} \forall i, \forall j$.*

Theorem 6 (Properties of Matrix Operators). *Define matrices A, B, C of the same size and let $c, d \in \mathbb{R}$. Then the following properties hold:*

1. *Commutativity: $A + B = B + A$.*
2. *Associativity: $A + (B + C) = (A + B) + C$.*
3. *Linearity: $c(A + B) = cA + cB$.*
4. *Linearity: $(c + d)A = cA + dA$.*
5. *$c(dA) = (cd)A = d(cA)$.*
6. *$A + 0 = 0 + A = A$.*
7. *$A - A = 0$.*
8. *$0A = 0$.*

Proof. To show equality of matrices, we have to show their size is the same and that their corresponding entries match (see Definition 30). The proofs for the above theorems are rather trivial, and we show the associativity law (other proofs are of the same stripe). Proof of associativity: Let $A = (a_{ij}), B = (b_{ij}), C = (c_{ij})$, then

$$A + (B + C) = (a_{ij}) + (B + C) \tag{36}$$

$$= (a_{ij}) + (b_{ij} + c_{ij}) \tag{37}$$

$$= (a_{ij} + b_{ij}) + (c_{ij}) \tag{38}$$

$$= (A + B) + (c_{ij}) \tag{39}$$

$$= (A + B) + C. \tag{40}$$

That is, we rely on the associativity on addition of real numbers to prove the associativity on addition of matrices. Finally, see that their sizes match. \square

¹note that the matrix subtraction can be defined as the addition of a matrix A with a matrix B that has first been operated on a by scalar multiplication of $c = -1$.

Definition 31 (Matrix Multiplication). For matrices $A = (a_{ij})_{m \times p}$, $B = (b_{ij})_{p \times n}$, the matrix product AB is defined to be the $m \times n$ matrix s.t.

$$C = A \times B = (c_{ij})_{m \times n} = \sum_{k=1}^p a_{ik}b_{kj}. \quad (41)$$

The matrix multiplication AB is only possible when $\text{ncols}(A) = \text{nrows}(B)$.

Exercise 8. Show that matrix multiplication (Definition 31) is not commutative.

Proof. Prove by counterexample. For matrices

$$A = \begin{pmatrix} -1 & 0 \\ 2 & 3 \end{pmatrix}, \quad B = \begin{pmatrix} 1 & 2 \\ 3 & 0 \end{pmatrix}, \quad (42)$$

see that

$$AB = \begin{pmatrix} -1 & -2 \\ 11 & 4 \end{pmatrix} \neq \begin{pmatrix} 3 & 6 \\ -3 & 0 \end{pmatrix} = BA. \quad (43)$$

□

Since the matrix multiplication is not commutative, when describing in words, we say that AB is the pre-multiplication of A to B and BA as the post-multiplication of A to B to prevent ambiguity.

Theorem 7 (Properties of Matrix Multiplication). Matrix multiplication (Definition 31) satisfies the following properties (we assume trivially that the size of the matrices are appropriate such that the matrix multiplication is legitimate) :

1. *Associativity:* $A(BC) = (AB)C$.
2. *Distributivity:* $A(B_1 + B_2) = AB_1 + AB_2$.
3. $c(AB) = (cA)B = A(cB)$.
4. $A0 = 0$, and $0A = 0$.
5. For identity matrix (Definition 25) of appropriate size, $A\mathbb{1} = \mathbb{1}A = A$.

Proof. Proof of the asserted statements follow directly from their definitions of matrices and matrix multiplications (Definitions 19, 31) and computing the resulting entries componentwise via the laws of algebra on real numbers (additionally, we also have to show that the sizes on the LHS and RHS are matching). □

Definition 32 (Powers of Square Matrices). For square matrix A and natural number $n \geq 0$, the power of A can be written

$$A^n = \begin{cases} \mathbb{1} & \text{if } n = 0, \\ \underbrace{AA \cdots A}_n & \text{if } n \geq 1. \end{cases} \quad \text{\small } n \text{ number of times} \quad (44)$$

By associativity, $A^m A^n = A^{m+n}$. By non-commutativity $(AB)^n \neq A^n B^n$. See Theorem 7 for statements on properties of matrix multiplications.

Exercise 9. Show that if $AB = BA$, then $(AB)^k = A^k B^k$.

Proof. We proof by induction. Base case is when $k = 1$, so $(AB)^1 = AB = A^1B^1$. This statement is trivial. Now assume $(AB)^j = A^jB^j$ for $j < k$. Then $(AB)^{j+1} = (AB)^jAB = A^jB^jAB$. Define the swap operator $\psi : BA \rightarrow AB$, then apply $\psi^j(B^jA)$ to get AB^j . Then we have $A^j\psi^j(B^jA)B = A^jAB^jB = A^{j+1}b^{j+1}$ and by induction we are done. \square

We may express rows, columns and even submatrices of a matrix by grouping together different entities. Here we show some examples.

Exercise 10 (Expressing Matrices as Block Matrices of Rows and Columns). For matrix $A = \begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{pmatrix}$,

$B = \begin{pmatrix} 1 & 1 \\ 2 & 3 \\ -1 & 2 \end{pmatrix}$, we may write

$$A = \begin{pmatrix} a_1 \\ a_2 \end{pmatrix}, \quad B = \begin{pmatrix} b_1 & b_2 \end{pmatrix}, \quad (45)$$

$$a_1 = \begin{pmatrix} 1 & 2 & 3 \end{pmatrix}, \quad a_2 = \begin{pmatrix} 4 & 5 & 6 \end{pmatrix}, \quad (46)$$

$$b_1 = \begin{pmatrix} 1 \\ 2 \\ -1 \end{pmatrix}, \quad b_2 = \begin{pmatrix} 1 \\ 3 \\ 2 \end{pmatrix}. \quad (47)$$

See that the following relationships hold by direct computation

$$AB = \begin{pmatrix} Ab_1 & Ab_2 \end{pmatrix} = \begin{pmatrix} a_1B \\ a_2B \end{pmatrix}. \quad (48)$$

Exercise 11 (Block Matrix Operations). Let A be $m \times n$ matrix, and B_1, B_2 be $n \times p, n \times q$ matrices, C_1, C_2 be $r \times m$ matrices, and D_1, D_2 be $s \times m, t \times m$ matrices respectively. See which of the following block operations are valid:

1. $A \begin{pmatrix} B_1 & B_2 \end{pmatrix} = \begin{pmatrix} AB_1 & AB_2 \end{pmatrix}$.

2. $\begin{pmatrix} C_1 & C_2 \end{pmatrix} A = \begin{pmatrix} C_1A & C_2A \end{pmatrix}$.

3. $\begin{pmatrix} D_1 \\ D_2 \end{pmatrix} A = \begin{pmatrix} D_1A \\ D_2A \end{pmatrix}$.

Proof. Refer to Exercise 10 for operations on matrix blocks written as rows and columns.

1. If we write $B_1 = \begin{pmatrix} b_1 & \cdots & b_p \end{pmatrix}, B_2 = \begin{pmatrix} c_1 & \cdots & c_q \end{pmatrix}$. Then

$$A \begin{pmatrix} B_1 & B_2 \end{pmatrix} = \begin{pmatrix} Ab_1 & \cdots & Ab_p & Ac_1 & \cdots & Ac_q \end{pmatrix} \quad (49)$$

and the relation is valid.

2. The matrix sizes do not permit a valid matrix operation.

3. If we let $D_1 = \begin{pmatrix} d_1 \\ \dots \\ d_s \end{pmatrix}$, $D_2 = \begin{pmatrix} f_1 \\ \dots \\ f_t \end{pmatrix}$, then

$$\begin{pmatrix} D_1 \\ D_2 \end{pmatrix} = \begin{pmatrix} d_1 \\ \dots \\ d_s \\ f_1 \\ \dots \\ f_t \end{pmatrix}. \quad (50)$$

Then we have

$$\begin{pmatrix} D_1 \\ D_2 \end{pmatrix} A = \begin{pmatrix} d_1 A \\ \dots \\ d_s A \\ f_1 A \\ \dots \\ f_t A \end{pmatrix} \quad (51)$$

and the relation is valid. □

Recall the augmented matrix representation of linear systems (see Definition 9). We may define an equivalent form.

Definition 33 (Matrix Representation of Linear System). *For system of linear equations*

$$\forall j \in [m], \quad a_{j1}x_1 + a_{j2}x_2 + \dots + a_{jn}x_n = b_j, \quad (52)$$

we may represent the linear system by matrix multiplication

$$\underbrace{\begin{pmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \dots & \dots & \dots & \dots \\ a_{m1} & a_{m2} & \dots & a_{mn} \end{pmatrix}}_A \underbrace{\begin{pmatrix} x_1 \\ x_2 \\ \dots \\ x_n \end{pmatrix}}_x = \underbrace{\begin{pmatrix} b_1 \\ b_2 \\ \dots \\ b_m \end{pmatrix}}_b. \quad (53)$$

Then we say that A is the coefficient matrix, x is the variable matrix and that b is the constant matrix for the linear system specified. A solution to the linear system is a $n \times 1$ column matrix

$$u = \begin{pmatrix} u_1 \\ u_2 \\ \dots \\ u_n \end{pmatrix} \quad (54)$$

where $Au = b$. If we treat $A = \begin{pmatrix} c_1 & c_2 & \dots & c_n \end{pmatrix}$ where c_i represents the i -th column of A , then we may write

$$c_1x_1 + c_2x_2 + \dots + c_nx_n = \sum_{j=1}^n c_jx_j = b. \quad (55)$$

That is, the constant matrix is a linear combination of the columns of the coefficient matrix, where the weights are determined via the variable matrix.

Definition 34 (Matrix Transpose). For matrix $A = (a_{ij})_{m \times n}$, the matrix transpose of A is written $A' = (a'_{ij})_{n \times m}$ where the entry $a'_{ij} = a_{ji}$.

See that the rows of A are the columns of A' and vice versa. See that a square matrix A is symmetric (Definition 27) iff $A = A'$.

Theorem 8 (Properties of the Matrix Transpose). The matrix transpose follows the following properties

1. $(A')' = A$.
2. $(A + B)' = A' + B'$.
3. For $c \in \mathbb{R}$, $(cA)' = cA'$.
4. $(AB)' = B'A'$.

Proof. The proof of the first three parts are fairly straightforward by direct computation of the algebraic properties of real numbers that follow from their Definitions. We show the last assertion. Denote the sizes of matrix A to be $m \times n$ and that of B to be $n \times p$ so that the matrix multiplications (Definition 31) are defined. Then AB has size $m \times p$, so that its transpose has size $p \times m$. B' has size $p \times n$, A' has size $n \times m$, so $B'A'$ has size $p \times m$. We show they are componentwise equivalent. Since $(AB)_{ij} = \sum_l a_{il}b_{lj}$. Then $(AB)'_{ij} = \sum_l a_{jl}b_{li}$. On the other hand, we have $A'_{ij} = a_{ji}, B'_{ij} = b_{ji}$, so that $(B'A')_{ij} = \sum_l b'_{il}a'_{lj} = \sum_l b_{li}a_{jl}$. We have showed that the corresponding entries are the same. \square

3.1.2.2 Invertibility of Matrices

Definition 35 (Invertibility of Square Matrix). Let A be square matrix of order n (Definition 22), then we say that A is invertible if \exists square matrix B of order n s.t. $AB = \mathbb{1}_n = BA$. The matrix B is said to be the inverse of A . We denote this A^{-1} . There is no ambiguity; we shall see that the inverse of a matrix is unique (Theorem 9).

Definition 36 (Singularity of Square Matrix). A matrix that does not have an inverse (Definition 35) is said to be singular.

Exercise 12. Show that the matrix $A = \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix}$ is singular.

Proof. Suppose not. Then let the inverse be $B = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$. Then by Definition 35, we have

$$BA = \mathbb{1} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} a+b & 0 \\ c+d & 0 \end{pmatrix}. \quad (56)$$

Then $1 = 0$. Contradiction. \square

Theorem 9 (Uniqueness of Inverses). If B, C are inverses of square matrix A , then $B = C$.

Proof. Write

$$AB = \mathbb{1} \implies CAB = C\mathbb{1} \implies \mathbb{1}B = C \implies B = C. \quad (57)$$

\square

Exercise 13 (Conditions for Invertibility of Square Matrix Order Two). *In the case for square matrix A of order two, denote*

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}. \quad (58)$$

State the conditions for invertibility and find the matrix inverse.

Proof. Define $B = \begin{pmatrix} \frac{d}{ad-bc} & \frac{-b}{ad-bc} \\ \frac{-c}{ad-bc} & \frac{a}{ad-bc} \end{pmatrix}$, which is defined only if $ad - bc \neq 0$. We may compute directly the matrices $AB = BA = \mathbb{1}$ (we show how to explicitly compute matrix inverses such as B later on). \square

Theorem 10 (Properties of Matrix Inverse). *Let A, B be two invertible matrices (Definition 35), and $c \neq 0, c \in \mathbb{R}$. Then the following properties hold*

1. cA is invertible, in particular $(cA)^{-1} = \frac{1}{c}A^{-1}$.
2. A' is invertible, and $(A')^{-1} = (A^{-1})'$.
3. A^{-1} is invertible and $(A^{-1})^{-1} = A$.
4. AB is invertible and $(AB)^{-1} = B^{-1}A^{-1}$.

Proof. -

1. We can write

$$(cA)\left(\frac{1}{c}A^{-1}\right) = \begin{pmatrix} c & 1 \\ c & c \end{pmatrix} AA^{-1} = \mathbb{1}, \quad (59)$$

$$\left(\frac{1}{c}A^{-1}\right)(cA) = \left(\frac{1}{c}\right)A^{-1}A = \mathbb{1}, \quad (60)$$

and the result immediately follows.

2. We show this by verifying that $(A^{-1})'$ is the inverse of A' , which confirms the assertion that A' is invertible. In particular, by properties of matrix transpose (Theorem 8), write

$$A'(A^{-1})' = (A^{-1}A)' = \mathbb{1}' = \mathbb{1}, \quad (61)$$

$$(A^{-1})'A' = (AA^{-1})' = \mathbb{1}' = \mathbb{1}. \quad (62)$$

Then A' is invertible, and the inverse is $(A^{-1})'$.

3. See that $A^{-1}A = \mathbb{1}, AA^{-1} = \mathbb{1}$ and by definition of inverse (Definition 35), the result follows.
4. Since A, B invertible, write

$$(AB)(B^{-1}A^{-1}) = AB B^{-1} A^{-1} = A \mathbb{1} A^{-1} = AA^{-1} = \mathbb{1}. \quad (63)$$

Also

$$(B^{-1}A^{-1})(AB) = \mathbb{1} \quad (64)$$

by similar reasoning.

\square

Definition 37 (Negative Powers of a Square Matrix). ?? For an invertible matrix A , we may define negative powers for a square matrix given $n \in \mathbb{Z}^+$ as the matrix power (Definition 32) of the inverse. That is,

$$A^{-n} = (A^{-1})^n. \quad (65)$$

See that if A^n is invertible, then $(A^n)^{-1} = A^{-n}$ for any $n \in \mathbb{Z}$.

3.1.2.3 Elementary Matrices

One may notice that the elementary row operations (see Definition 10) may be considered as the pre-multiplication of some matrix to the matrix being operated on. For instance, see that

$$A = \begin{pmatrix} 1 & 0 & 2 & 3 \\ 2 & -1 & 3 & 6 \\ 1 & 4 & 4 & 0 \end{pmatrix} \xrightarrow{2R_2} B = \begin{pmatrix} 1 & 0 & 2 & 3 \\ 4 & -2 & 6 & 12 \\ 1 & 4 & 4 & 0 \end{pmatrix}, \quad (66)$$

and see that

$$\underbrace{\begin{pmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 1 \end{pmatrix}}_{E_1} A = B. \quad (67)$$

In particular, the ERO kR_i (Definition 10) may be performed by the pre-multiplication of matrix E_k , where E_k is a diagonal matrix (Definition 23) of order $nrows(A)$, where all the entries along the diagonal are one except for the i -th row, where the entry is k . If $k \neq 0$, and since performing $kR_i, \frac{1}{k}R_i$ in sequence gives us back the same matrix - see that the E_k is invertible and that E_k^{-1} is the diagonal matrix with all ones along the diagonal except for $\frac{1}{k}$ entry on the i -th row.

Next, observe the ERO $R_i \leftrightarrow R_j$ (see Definition 10) on the following instance:

$$A = \begin{pmatrix} 1 & 0 & 2 & 3 \\ 2 & -1 & 3 & 6 \\ 1 & 4 & 4 & 0 \end{pmatrix} \xrightarrow{R_2 \leftrightarrow R_3} B = \begin{pmatrix} 1 & 0 & 2 & 3 \\ 1 & 4 & 4 & 0 \\ 2 & -1 & 3 & 6 \end{pmatrix}, \quad (68)$$

and see that

$$\underbrace{\begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}}_{E_2} A = B. \quad (69)$$

In particular, the ERO $R_i \leftrightarrow R_j$ (Definition 10) may be performed by the pre-multiplication of matrix E_s , where E_s is a matrix that began with an identity matrix (Definition 25) of order $nrows(A)$ and has gone through precisely the row swap $R_i \leftrightarrow R_j$. See that swapping rows i and j and then swapping again rows i and j gives us back the original matrix. Then $E_s = E_s^{-1}$.

Last but not least, observe the ERO $R_i + kR_j$ (see Definition 10) on the following instance:

$$A = \begin{pmatrix} 1 & 0 & 2 & 3 \\ 2 & -1 & 3 & 6 \\ 1 & 4 & 4 & 0 \end{pmatrix} \xrightarrow{R_3 + 2R_1} B = \begin{pmatrix} 1 & 0 & 2 & 3 \\ 1 & 4 & 4 & 0 \\ 3 & 4 & 8 & 6 \end{pmatrix}, \quad (70)$$

and see that

$$\underbrace{\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 2 & 0 & 1 \end{pmatrix}}_{E_3} A = B. \quad (71)$$

In particular, the ERO $R_i + kR_j$ (Definition 10) may be performed by the pre-multiplication of matrix E_l , where E_l is a matrix that began with an identity matrix (Definition 25) of order $nrows(A)$ and has gone through precisely the row addition $R_i + kR_j$. As before, the (triangular, Definition 28) matrix E_l is invertible and E_l^{-1} represents the row-swap operation $R_i - kR_j$.

Definition 38 (Elementary Matrix). *A square matrix (Definition 22) that can be obtained from an identity matrix (Definition 25) from a single elementary row operation (Definition 38) is called an elementary matrix.*

We saw that all elementary matrices (Definition 38) are invertible, and their inverses are also elementary matrices. The discussions thus far allow us to arrive at the following result:

Lemma 3. *The EROs (Definition 10) performed on arbitrary matrices correspond precisely to the pre-multiplication of an elementary matrix (Definition 38) obtained from performing the ERO on the identity matrix (Definition 25).*

For a series of EROs applied in sequence O_1, O_2, \dots, O_k , (Definition 10) applied on A , s.t.

$$A \xrightarrow{O_1} \xrightarrow{O_2} \dots \xrightarrow{O_k} B, \quad (72)$$

and their corresponding elementary matrices E_1, \dots, E_k , see that the relation

$$E_k E_{k-1} \dots E_1 A = B \quad (73)$$

must hold. By the invertibility, we have the relation

$$A = E_1^{-1} E_2^{-1} \dots E_k^{-1} B. \quad (74)$$

Exercise 14. *Prove the solution-set equivalency asserted in Theorem 4.*

Proof. We show that if there are two row equivalent (Definition 11) augmented matrices (Definition 9) $(A|b), (C|d)$, then the linear systems $Ax = b, Cx = d$ share solution set. By Lemma 3, see that $\exists E$ s.t.

$$(C|d) = E(A|b) = (EA|Eb), \quad (75)$$

which is valid by Exercise 11. Then if $Au = b$ (that is if u is solution), then

$$Au = b \implies E Au = E b \implies C u = d. \quad (76)$$

On the other hand, if $Cv = d$, then

$$Cv = d \implies E Av = E b \implies E^{-1} E Av = E^{-1} E b \implies \mathbb{I} Av = \mathbb{I} b \implies Av = b. \quad (77)$$

They share solution set. □

Theorem 11 (Invertibility of Square Matrices, 1). *If A is square matrix order n , then the following statements are equivalent:*

1. A is invertible.
2. $Ax = 0$ has only the trivial solution.
3. RREF of A is identity $\mathbb{1}$ matrix.
4. A can be expressed as $\Pi_i^n E_i$, where E_i are elementary matrices.

Proof. It turns out that this theorem shows an easy way to compute the inverses of an invertible matrix A . To show

- (i) $1 \implies 2$: if $Ax = 0$, then

$$x = \mathbb{1}x = A^{-1}Ax = A^{-1}0 = 0, \quad (78)$$

where the last step follows from Theorem 7.

- (ii) $2 \implies 3$: $Ax = 0$ is the only trivial solution. Since A is square, $nrows(A) = ncols(A)$, then by Lemma 2, the RREF of A or $(A|0)$ has no zero rows. By definition of RREF (Definition 17), the RREF of A is identity (Definition 25).

- (iii) $3 \implies 4$: Since RREF of A is $\mathbb{1}$, by Lemma 3, $\exists E_i, i \in [k]$ s.t.

$$E_k E_{k-1} \cdots E_1 A = \mathbb{1}. \quad (79)$$

Then $A = (E_k \cdots E_1)^{-1} \mathbb{1}$, and by inverse properties, Theorem 10, we have

$$A = E_1^{-1} \cdots E_k^{-1}. \quad (80)$$

- (iv) $4 \implies 1$: Since A is product of invertible elementary matrices, A is invertible by Theorem 10.

□

Theorem 12 (Cancellation Law). *Let A be an invertible matrix (Definition 35) of order m , then the following properties hold:*

1. $AB_1 = AB_2 \implies B_1 = B_2$.
2. $C_1A = C_2A \implies C_1 = C_2$.

This does not hold for matrix A when it is non-singular.

Proof. For first the part,

$$AB_1 = AB_2 \implies AB_1 - AB_2 = 0 \implies A(B_1 - B_2) = 0. \quad (81)$$

Then since A is invertible, the HLS has only trivial solution by Theorem 11, so $B_1 - B_2 = 0$ and it follows that $B_1 = B_2$. For part 2, write

$$(C_1 - C_2)A = 0 \implies (C_1 - C_2)AA^{-1} = 0 \implies (C_1 - C_2)\mathbb{1} = 0, \quad (82)$$

and the result follows. □

We may use the discussions in Theorem 11 to compute the matrix inverse. For A satisfying $E_k \cdots E_1 A = \mathbb{1}$, see that $E_k \cdots E_1 = A^{-1}$ by the post multiplication of A^{-1} to both the RHS and LHS. Recall this is valid, since we are guaranteed the invertibility of A . Furthermore, this is unique (Theorem 9). Consider the $n \times 2n$ matrix $(A|\mathbb{1}_n)$. Then

$$E_k \cdots E_1(A|\mathbb{1}) = (E_k \cdots E_1 A | E_k \cdots E_1 \mathbb{1}) \quad (83)$$

$$= (\mathbb{1} | A^{-1}). \quad (84)$$

That is, to the augmented matrix $(A|\mathbb{1})$, if we perform Gauss-Jordan elimination (see Theorem 5) and get RREF $\mathbb{1}$ on the LHS of $|$, the RHS is A^{-1} . Otherwise, A is singular and does not have an inverse. The following theorem shows us that given square matrices A, B - when we are to verify $A^{-1} = B$, we are only required to check one of $AB = \mathbb{1}$ or $BA = \mathbb{1}$.

Theorem 13. *Let A, B be square matrix order n . If $AB = \mathbb{1}$, then A, B are both invertible and*

$$A^{-1} = B, \quad B^{-1} = A, \quad BA = \mathbb{1}. \quad (85)$$

Proof. Consider HLS (Definition 18) $Bx = 0$. If $Bu = 0$, then

$$ABu = \mathbb{1}u \implies A0 = u \implies 0 = u. \quad (86)$$

Then $Bx = 0$ only has the trivial solution. By Theorem 11, B is invertible. Since B is invertible:

$$AB = \mathbb{1} \implies ABB^{-1} = \mathbb{1}B^{-1} \implies A\mathbb{1} = B^{-1} \implies A = B^{-1}. \quad (87)$$

So A is invertible by Theorem 11 and $A^{-1} = (B^{-1})^{-1} = B$, $BA = BB^{-1} = \mathbb{1}$. \square

Exercise 15. *For square matrix A , given $A^2 - 3A - 6\mathbb{1} = 0$, show that A is invertible.*

Proof. Since we may write

$$A(A - 3\mathbb{1}) = A^2 - 3A\mathbb{1} = A^2 - 3A = 6\mathbb{1}, \quad (88)$$

then $A \left[\frac{1}{6}(A - 3\mathbb{1}) \right] = \mathbb{1}$, and it follows that A is invertible from Theorem 13. \square

Theorem 14 (Singularity of Matrix Products). *Let A, B be two square matrices of order n . Then if A is singular, AB, BA are both singular (see Definition 14).*

Proof. Suppose not. Then AB is invertible, and let $C = (AB)^{-1}$. Then we may write

$$ABC = \mathbb{1}, \quad (89)$$

then A is invertible since $A^{-1} = BC$ by Theorem 13. This is contradiction. \square

Theorem 15 (Elementary Column Operations). *See from Lemma 3 that the pre-multiplication of an elementary matrix to matrix A is equivalent to doing an ERO on $A_{p \times m}$ matrix. Let E_k, E_s, E_l be elementary matrices corresponding to $kR_i, R_i \leftrightarrow R_j, R_i + kR_j$ respectively (see Definition 10). Then, the post multiplication of the matrices E_k, E_s, E_l correspond to*

1. *Multiplying the i -th column of A by k .*
2. *Swap columns i, j in A .*
3. *Add k times j -th column of A to i -th column of A*

respectively and let these be known collectively as elementary column operations (ECOs). They shall be denoted $kC_i, C_i \leftrightarrow C_j, C_i + kC_j$.

3.1.2.4 Matrix Determinants

It turns out that whether a square matrix is invertible (Definition 35) depends on a quantity of the matrix known as the determinant. We define this recursively.

Definition 39 (Determinants and Cofactors). *For square matrix A order n , let M_{ij} be an $(n-1) \times (n-1)$ square matrix obtained from A by deleting the i -th and j -th column. Then the determinant of A is defined as*

$$\det(A) = \begin{cases} a_{11} & \text{if } n = 1, \\ a_{11}A_{11} + a_{12}A_{12} + \cdots + a_{1n}A_{1n} & \text{if } n > 1, \end{cases} \quad (90)$$

where $A_{ij} = (-1)^{i+j} \det(M_{ij})$. The number A_{ij} is known as the ij -cofactor of A . This method of recursively computing matrix determinants are known as cofactor expansion. Often, we adopt the equivalent notations for determinant of A :

$$\det(A) = \begin{vmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{vmatrix}. \quad (91)$$

Exercise 16 (Cofactor Expansion Examples). *Here we show some instances of co-factor expansion. When the matrix is 2×2 , then we have a general form*

$$A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}. \quad (92)$$

Then see that the determinant by cofactor expansion

$$a \cdot (-1)^{1+1} \det(d) + b \cdot (-1)^{1+2} \det(c) = ad - bc. \quad (93)$$

Then for larger matrices, we may use these sub-results. For instance, the determinant for $B = \begin{pmatrix} -3 & -2 & 4 \\ 4 & 3 & 1 \\ 0 & 2 & 4 \end{pmatrix}$

via cofactor expansion is obtained

$$\det(B) = (-3) \begin{vmatrix} 3 & 1 \\ 2 & 4 \end{vmatrix} - (-2) \begin{vmatrix} 4 & 1 \\ 0 & 4 \end{vmatrix} + 4 \begin{vmatrix} 4 & 3 \\ 0 & 2 \end{vmatrix} = -3(3 \cdot 4 - 1 \cdot 2) + 2(4 \cdot 4 - 1 \cdot 0) + 4(4 \cdot 2 - 3 \cdot 0) = 34. \quad (94)$$

Result 3 (Cofactor Expansion Invariance). *For square matrix A order n , $\det(A)$ (Definition 39) may be found via cofactor expansion along any row or any column.*

Theorem 16 (Cofactor Expansion of Triangular Matrices). *For triangular matrix A , the determinant A is equal to the product of diagonal entries of A .*

Proof. By definition of triangular matrices (Definition 28), both the upper triangular and lower triangular has a row that is all zeros except for possibly a singly entry (the diagonal itself). That is, an upper triangular takes general form

$$A = \begin{pmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ 0 & a_{22} & \cdots & a_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ 0 & 0 & \cdots & a_{nn} \end{pmatrix} \quad (95)$$

Additionally, since matrix is square, cofactor expansion along the last row, last entry has the term $(-1)^{i+i} = 1$. By Result 3, see that if we apply recursively the cofactor expansion along the last row, we obtain just the product of the diagonal entries. A similar reasoning is applied if the matrix is lower triangular. \square

See that the determinant of $\mathbb{1}$ is one by Theorem 16.

Theorem 17 (Determinant of Matrix Transpose). *For square matrix A of order n , $\det(A) = \det(A')$.*

Proof. We prove by induction. The base case is for a matrix containing a single scalar value. This is trivially true, since the transpose of a matrix 1×1 is itself. Next, assume $\det(A) = \det(A')$ for any square matrix A order k . We show this holds for $(k+1) \times (k+1)$ matrix. In particular, by cofactor expansion along the first row of A , obtain

$$\det(A) = \sum_i^n (-1)^{1+i} a_{1i} \det(M_{1i}). \quad (96)$$

Next perform, cofactor expansion along the first column of A' , then

$$\det(A') = \sum_i^n (-1)^{1+i} a_{1i} \det(M'_{1i}). \quad (97)$$

By induction, $\det(A) = \det(A')$ since $\det(M_{ij}) = \det(M'_{ij})$. \square

Theorem 18 (Determinant of Repeated Row/Column Matrix). *The determinant of a square matrix with two identical rows is zero. The determinant of a square matrix with two identical columns is zero.*

Proof. We prove by induction. The base case is for matrix A size 2×2 . For matrix $A = \begin{pmatrix} a & b \\ a & b \end{pmatrix}$, by Exercise 16 we have $\det(A) = ab - ab = 0$. Assume that for $k < n$, $\det(A)$ size $k \times k$ with repeated row is zero. Then consider a $(k+1) \times (k+1)$ matrix with row i equivalent to row j , $i \neq j$. Then by cofactor expansion along some row m that is neither i nor j , we have

$$\det(A) = a_{m1}A_{m1} + \cdots + a_{m,k+1}A_{m,k+1} \quad (98)$$

A_{mr} is the cofactor $(-1)^{m+r} \det(M_{mr})$, which has identical rows and by inductive assumption has determinant zero. Then $\det(A) = 0$ and we are done. Since $\det(A) = \det(A')$, a square matrix with two identical columns has transpose with two identical rows and the result follows. \square

Theorem 19. *Recall the notations for EROs (Definition 10) and correspondence to their elementary matrices (Lemma 3). Let A be square matrix, and*

- (i) B be a square matrix obtained by some ERO kR_i . Then, $\det(B) = k\det(A)$.
- (ii) B be a square matrix obtained by some ERO $R_i \leftrightarrow R_j$. Then, $\det(B) = -\det(A)$.
- (iii) B be a square matrix obtained by some ERO $R_i + kR_j$. Then, $\det(B) = \det(A)$.
- (iv) E be some elementary matrix with size $n_{\text{rows}}(A) \times n_{\text{rows}}(A)$. Then $\det(EA) = \det(E)\det(A)$.

It turns out that this is quite useful because the determinants of elementary matrices are fairly easy to compute. Only the elementary matrix corresponding to the swap operation is a non-triangular matrix (Definition 28), but even the swap operation has corresponding elementary matrix where each sub-square matrix has row/column with only a single scalar entry of one and the rest zero.

Proof. We do not prove this theorem but this may be obtained via the rather mechanical cofactor expansion and definition of matrix determinants (Definition 39). \square

Theorem 20. Recall the notations for CROs (Definition 15) and correspondence to their elementary matrices. Let A be square matrix, and

- (i) B be a square matrix obtained by some CRO kC_i . Then, $\det(B) = k\det(A)$.
- (ii) B be a square matrix obtained by some CRO $C_i \leftrightarrow C_j$. Then, $\det(B) = -\det(A)$.
- (iii) B be a square matrix obtained by some CRO $C_i + kC_j$. Then, $\det(B) = \det(A)$.
- (iv) E be some elementary matrix with size $n_{\text{rows}}(A) \times n_{\text{rows}}(A)$. Then $\det(AE) = \det(E)\det(A)$.

Theorem 21 (Determinants and Invertibility). Square matrix A is invertible iff $\det(A) \neq 0$.

Proof. For square matrix A we may write $B = E_k \cdots E_1 A$, where each E_i is elementary matrix and B is RREF. By Theorem 19, $\det(B) = \det(A) \prod_{i=1}^k \det(E_i)$. By Theorem 11, $B = \mathbb{1}$, and $\det(B) = 1$. Then $\det(A) \neq 0$ since $\nexists i$ s.t. $\det(E_i) = 0$. If A is singular, then B has zero row (Definition 13). By cofactor expansion (Theorem 3) along the zero row, $\det(B) = 0$, then $\det(A) = 0$ since again, $\nexists i$ s.t. $\det(E_i) = 0$. \square

Theorem 22. For square matrix A, B order n and $c \in \mathbb{R}$, the following hold:

1. $\det(cA) = c^n \det(A)$,
2. $\det(AB) = \det(A)\det(B)$,
3. If A is invertible, then $\det(A^{-1}) = \frac{1}{\det(A)}$.

Proof. -

1. This follows from Theorem 19 and seeing that cA is multiplying each of the n rows by c .
2. If A is singular, then AB is singular by Theorem 14. Then $\det(AB) = \det(A)\det(B) = 0$. Otherwise, matrix A may be represented by product of elementary matrices s.t.

$$\det(AB) = \det(E_1 \cdots E_k B) = \det(B) \prod_{i=1}^k \det(E_i) = \det(B)\det(A). \quad (99)$$

3. Follows since $\det(A)\det(A^{-1}) = \det(AA^{-1}) = \det(\mathbb{1}) = 1$. The first equality follows from part 2. \square

Definition 40 (Classical Adjoint). Let A be square matrix order n . Then the (classical) adjoint of A is $n \times n$ matrix

$$\text{adj}(A) = \begin{pmatrix} A_{11} & A_{12} & \cdots & A_{1n} \\ A_{21} & A_{22} & \cdots & A_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ A_{n1} & A_{n2} & \cdots & A_{nn} \end{pmatrix}', \quad (100)$$

where A_{ij} is (i,j) cofactor of A (Definition 39).

Theorem 23 (Inverse by Adjoint). *Let A be square matrix, then if A is invertible, we have*

$$A^{-1} = \frac{1}{\det(A)} \text{adj}(A). \quad (101)$$

Proof. Let $B = A \cdot \text{adj}(A)$, then

$$b_{ij} = a_{i1}A'_{1j} + a_{i2}A'_{2j} + \cdots + a_{in}A'_{nj} \quad (102)$$

$$= a_{i1}A_{j1} + a_{i2}A_{j2} + \cdots + a_{in}A_{jn}. \quad (103)$$

By definition of cofactor expansion (see Definition 39 and Theorem 3), see that

$$\det(A) = b_{ii}. \quad (104)$$

By Equation 103, see that when $i \neq j$, then b_{ij} is the cofactor expansion along the row j of matrix A where the entries of row i, j are both $a_{i1}, a_{i2}, \dots, a_{in}$. Then by Theorem 18, $b_{ij} = 0$ if $i \neq j$. Then

$$A \cdot \text{adj}(A) = \det(A) \mathbb{1} \implies \frac{1}{\det(A)} A \cdot \text{adj}(A) = \mathbb{1}. \quad (105)$$

Then the result follows. \square

Theorem 24 (Cramer's Rule). *Suppose $Ax = b$ is linear system (Definition 5), where A is square matrix order n . Then if A_i is the matrix obtained from replacing i -th column of A by b , and if A is invertible, then the system has unique solution*

$$x = \frac{1}{\det(A)} \begin{pmatrix} \det(A_1) \\ \det(A_2) \\ \dots \\ \det(A_n) \end{pmatrix}. \quad (106)$$

Since

$$Ax = b \leftrightarrow x = A^{-1}b = \frac{1}{\det(A)} \text{adj}(A) \cdot b, \quad (107)$$

then

$$x_i = \frac{b_1 A_{1i} + b_2 A_{2i} + \cdots + b_n A_{ni}}{\det(A)} = \frac{\det(A_i)}{\det(A)}. \quad (108)$$

Exercise 17. *For $A_{m \times n}, B_{n \times p}$ matrices, if $Bx = 0$ has infinitely many solutions, how many solutions does $ABx = 0$ have? What about if $Bx = 0$ has only the trivial solution?*

Proof. Suppose $Bx = 0$ has infinitely many solutions, and let this solution space be S . See that $\forall s \in S, ABs = A0 = 0$. There are at least as many solutions as Bx , and this is in fact infinitely many. On other hand, we cannot make comments about the solutions to $ABx = 0$ when $Bx = 0$ only has trivial solution. For instance, if $B = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$, the cases for matrix $A = \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix}$ and $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ give rise to a linear system with trivial solution and infinitely many solutions respectively. \square

Definition 41 (Trace). *For square matrix A of order n , the matrix trace denoted $\text{tr}(A)$ is the sum of entries along the diagonals of A . For A, B square matrix both of order n , $C_{m \times n}, D_{n \times m}$, we have*

1. that

$$\text{tr}(A + B) = \text{tr}(A) + \text{tr}(B). \quad (109)$$

2. that $tr(cA) = ctr(A)$.
3. that $tr(CD) = tr(DC)$.
4. that $\nexists A, B$ s.t. $AB - BA = \mathbb{1}$.

Proof. The first two properties are easy to proof by definitions of trace and matrix. For the third statement, see that

$$(CD)_{ii} = \sum_j^n c_{ij}d_{ji}, \quad (110)$$

$$tr(CD) = \sum_i^m \sum_j^n c_{ij}d_{ji} \quad (111)$$

$$= \sum_j^n \sum_i^m d_{ji}c_{ij}. \quad (112)$$

See that the RHS is precisely $tr(DC)$. Lastly, since $tr(AB - BA) = tr(AB) - tr(BA) = tr(AB) - tr(AB) = 0$ by the earlier parts and $tr(\mathbb{1}_n) = n$, it cannot be that $AB - BA = \mathbb{1}$. \square

Exercise 18 (Orthogonal Matrices). *A square matrix is an orthogonal matrix if*

$$AA' = \mathbb{1} = A'A. \quad (113)$$

Suppose A, B is square matrix order n and orthogonal, then show AB is orthogonal.

Proof. See that (by Theorem 6)

$$AB(AB)' = ABB'A' = A\mathbb{1}A' = AA' = \mathbb{1}, \quad (114)$$

and that

$$(AB)'AB = B'A'AB = B'\mathbb{1}B = B'B = \mathbb{1}. \quad (115)$$

\square

Orthogonal matrices are treated in Section 3.1.5.3.

Exercise 19 (Nilpotent Matrices). *A square matrix is a nilpotent matrix if $\exists k \in \mathbb{Z}^+$ s.t. $A^k = 0$. Let A, B be square matrices order n , and that $AB = BA$ with nilpotent matrix A . Show that AB is nilpotent. Show that we require the condition $AB \neq BA$.*

Proof. Let k be some constant s.t. $A^k = 0$. Then by Exercise 9 we have

$$(AB)^k = A^k B^k \implies 0B^k = 0, \quad (116)$$

so AB is nilpotent. No - we may prove by simple counterexample, say $A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, $B = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$. \square

Exercise 20. *Show that for diagonal matrix A , the power of the diagonal matrix A^k is diagonal matrix with entry a_{ii}^k , for $i \in [nrows(A)]$.*

Proof. Obtain this by simply writing out the mathematical induction proof. \square

Exercise 21. *Prove or disprove the following:*

1. If A, B diagonal matrices of same size, $BA = AB$.
2. If A is square matrix, and $A^2 = 0$, then $A = 0$.
3. If A is matrix s.t. $AA' = 0$, $A = 0$.
4. A, B invertible $\implies A + B$ invertible.
5. A, B singular $\implies A + B$ singular.

Proof. -

1. This statement is true. See that $AB_{ij} = a_{ii}b_{ii}$ and $BA_{ij} = b_{ii}a_{ii}$.

2. This statement is false by counterexample $A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$.

3. This statement is true. For matrix A size $m \times n$, AA' is square matrix $m \times m$. $AA'_{ii} = \sum_j^n a_{ij}a'_{ji} = \sum_j^n a_{ij}^2$ and this implies that if $AA' = 0$, $a_{ij} = 0$ for all values i, j . A must be zero matrix.

4. This statement is false by counterexample:

$$A = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad B = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}. \quad (117)$$

5. This statement is false by counterexample:

$$A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}. \quad (118)$$

□

Exercise 22. Let A be square matrix. Then

1. Show that if $A^2 = 0$, then $\mathbb{1} - A$ is invertible. Find the inverse.
2. Show that if $A^3 = 0$, then $\mathbb{1} - A$ is invertible. Find the inverse.
3. Find the relation at higher order powers.

Proof. -

1. Since

$$(\mathbb{1} - A)(\mathbb{1} + A) = \mathbb{1} - A^2 = \mathbb{1}, \quad (119)$$

then $\mathbb{1} - A$ is invertible with inverse $\mathbb{1} + A$.

2. See that

$$(\mathbb{1} - A)(\mathbb{1} + A + A^2) = \mathbb{1} - A^3 = \mathbb{1}, \quad (120)$$

so the inverse of $\mathbb{1} - A$ is $\mathbb{1} + A + A^2$.

3. As in previous parts, the general form matrix inverse of $\mathbb{1} - A$ where $A^n = 0$ is

$$\sum_{j=0}^{n-1} A^j. \quad (121)$$

□

Exercise 23. Suppose A, B is invertible square matrix order n , and that $A + B$ is invertible. Then show that $A^{-1} + B^{-1}$ is invertible and find $(A + B)^{-1}$.

Proof. If $A + B$ is invertible, then the matrix $(A(A + B)^{-1}B)$ must be invertible. Consider the inverse of this matrix, by Theorem 10 we have

$$(A(A + B)^{-1}B)^{-1} = B^{-1}(A + B)A^{-1} = (B^{-1}A + \mathbb{1})A^{-1} = B^{-1} + A^{-1}. \quad (122)$$

We have effectively shown that the inverse of $A^{-1} + B^{-1}$ exists and is $(A(A + B)^{-1}B)$. Then we may write

$$A(A + B)^{-1}B = (A^{-1} + B^{-1})^{-1} \quad (123)$$

$$A^{-1}A(A + B)^{-1}BB^{-1} = A^{-1}(A^{-1} + B^{-1})^{-1}B^{-1} = (A + B)^{-1} \quad (124)$$

and we are done. □

Exercise 24. Let A, P, D be square matrices s.t.

$$A = PDP^{-1}. \quad (125)$$

Show that $A^k = PD^kP^{-1}$ for all $k \in \mathbb{Z}^+$.

Proof. See that $A^k = PDP^{-1} \underbrace{PDP^{-1} \cdots PDP^{-1}}_{k \text{ times}}$. Then all the adjacent $P^{-1}P$ is identity and we arrive at PD^kP^{-1} . □

Exercise 25. Show that for matrix $A_{m \times n}, B_{n \times m}$, and $A \stackrel{\mathcal{R}}{\equiv} REF(A)$ with $REF(A)$ having some zero row, show that AB is singular.

Proof. If $A \stackrel{\mathcal{R}}{\equiv} REF(A)$ with $REF(A)$ having a zero row, then $A = E_k \cdots E_1 REF(A)$ for elementary matrices $E_i, i \in [k]$, and $AB = E_k \cdots E_1 REF(A)B$. It follows that $AB \stackrel{\mathcal{R}}{\equiv} REF(A)B$ and since $REF(A)$ has zero row, by the block matrix multiplication (Exercise 11) AB has $REF(AB)$ where $REF(AB)$ has zero row. This can never be row equivalent to $\mathbb{1}$, and by Theorem 11, AB is singular. □

Exercise 26. For matrix $A_{m \times n}$ and $m > n$, see if is possible for AB to be invertible where B is matrix size $n \times m$.

Proof. AB will always be singular. The REF of A has at most n non-zero rows, and since $m > n$, REF form of A has zero row. Then by the proof in Exercise 25, AB must be singular. □

Exercise 27. Let A be some 2×2 orthogonal matrix (Definition 18). Prove that

1. $\det(A) = \pm 1$,

2. $A = \begin{pmatrix} \cos(\theta) & -\sin(\theta) \\ \sin(\theta) & \cos(\theta) \end{pmatrix}$ for some $\theta \in \mathbb{R}$ if $\det(A) = 1$,

3. and otherwise $A = \begin{pmatrix} \cos(\theta) & \sin(\theta) \\ \sin(\theta) & \cos(\theta) \end{pmatrix}$.

Proof. -

1. $\det(\mathbb{1}) = \det(AA') = \det(A)\det(A') = \det(A)^2 = 1.$

2. For matrix $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$, if A is orthogonal, $A^{-1} = A'$. Then using invertibility by adjoint (Theorem 23), we can write

$$\begin{pmatrix} a & c \\ b & d \end{pmatrix} = \frac{1}{\det(A)} \begin{pmatrix} d & -b \\ -c & a \end{pmatrix} = \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}. \quad (126)$$

So $a = d, b = -c$ and by assumption $a^2 + c^2 = ad - bc$. Let $a = \cos(\theta), c = \sin(\theta)$, the result follows.

3. Follow part 2. with $a \rightarrow -d, b \rightarrow c.$

□

Exercise 28. Let A be invertible square matrix order n . Then

1. Show that $\text{adj}(A)$ is invertible.
2. Find $\det(\text{adj}(A)), \text{adj}(A)^{-1}$.
3. Show $\det(A) = 1 \implies \text{adj}(\text{adj}(A)) = A$.

Proof. -

1. By Theorem 23, we have

$$A \left[\frac{1}{\det(A)} \text{adj}(A) \right] = \mathbb{1} \implies \left[\frac{1}{\det(A)} A \right] \text{adj}(A) = \mathbb{1} \quad (127)$$

by Theorem 13.

2. By Theorem 22, since

$$\det(\mathbb{1}) = \left(\frac{1}{\det(A)} \right)^n \det(\text{adj}(A)) \det(A) = 1, \quad (128)$$

then $\det(\text{adj}(A)) = \det(A)^{n-1}$ and $\text{adj}(A)^{-1} = \frac{1}{\det(A)} A$.

3. From the general form $A \left[\frac{1}{\det(A)} \text{adj}(A) \right] = \mathbb{1}$, we can write

$$\text{adj}(A) \left[\frac{1}{\det(\text{adj}(A))} \text{adj}(\text{adj}(A)) \right] = \mathbb{1}. \quad (129)$$

Then by part 2, we have

$$\text{adj}(\text{adj}(A)) = \det(\text{adj}(A)) \text{adj}(A)^{-1} = \det(\text{adj}(A)) \frac{1}{\det(A)} A = \det(A)^{n-1} \det(A)^{-1} A = \det(A)^{n-2} A.$$

If $\det(A) = 1$, then it follows that

$$\text{adj}(\text{adj}(A)) = A. \quad (130)$$

□

Exercise 29. Prove or disprove the following statements.

1. A, B square matrices of order n satisfies $\det(A + B) = \det(A) + \det(B)$.
2. If A is square matrix, $\det(A + \mathbb{1}) = \det(A' + \mathbb{1})$.
3. A, B square matrices of order n and $A = PBP^{-1}$ for some invertible P satisfies $\det(A) = \det(B)$.
4. A, B, C square matrices of order and $\det(A) = \det(B)$ satisfies $\det(A + C) = \det(B + C)$.

Proof. -

1. This is false by counterexample:

$$A = \mathbb{1}_2, \quad B = -\mathbb{1}_2. \quad (131)$$

2. This is true, since $\det(A + \mathbb{1}) = \det((A + \mathbb{1})') = \det(A' + \mathbb{1})$.
3. This is true, since

$$\det(A) = \det(PBP^{-1}) = \det(P)\det(B)\det(P^{-1}) = \det(B)\det(P)\det(P^{-1}) = \det(B) \cdot 1. \quad (132)$$

4. This is false by counterexample:

$$A = -\mathbb{1}_2, \quad B = \mathbb{1}_2, \quad C = \mathbb{1}_2. \quad (133)$$

□

3.1.3 Vector Spaces

3.1.3.1 Finite Euclidean Spaces

A vector may be specified by the direction of the arrow, and its length specified by its magnitude. Two vectors are equal if they share direction and magnitude. If we denote a length of the vector u by $\|u\|$, then clearly the length of a scaled vector cu must be $c\|u\|$. The geometrical interpretations for vectors are somewhat elusive past three dimensional spaces, however, it should be noted that the theorems constructed in spaces of dimensions lower than three may be extended to higher finite dimensions, even if it may not be visualized.

Definition 42 (Vector and Coordinates). *A n -vector or ordered n -tuple of real numbers takes form*

$$(u_1, u_2, \dots, u_n) \quad (134)$$

where $u_i \in \mathbb{R}, i \in [n]$. The i -th component or coordinate of a vector is the entry u_i .

Definition 43 (Vector Terminologies). *Two n -vectors u, v are equal if $\forall i \in [n], u_i = v_i$. The vector $w = u + v$ is s.t. $\forall i \in [n], w_i = u_i + v_i$. Scalar multiple of vector is the operation for some $c \in \mathbb{R}, w = cu$ s.t. $\forall i \in [n], w_i = cu_i$. The negative of vector u is the scalar multiple of vector where $c = -1$. The subtraction of vector v from u is the addition of vector u to negative of vector v . A zero vector is one in which $\forall i \in [n], u_i = 0$.*

See that we may identify vectors as special cases of matrices, that is either the row vector or column vector (Definition 21).

Theorem 25 (Vector Operations). *For n -vector u, v, w , the following hold:*

1. $u + v = v + u$,
2. $u + (v + w) = (u + v) + w$,
3. $u + 0 = u = 0 + u$,
4. $u + (-u) = 0$,
5. $c(du) = (cd)u$,
6. $c(u + v) = cu + cv$,
7. $(c + d)u = cu + du$,
8. $1u = u$.

Proof. These properties follow from their definitions. Otherwise, see that vectors are matrices, and use the same result on matrices (i.e. Theorem 7, Definition 29 and Definition 31). \square

We give formal definitions for Euclidean spaces.

Definition 44 (Euclidean Space). *A Euclidean space is the set of all n -vectors of real numbers. This is denoted \mathbb{R}^n . When $n = 1$, we usually just write \mathbb{R} . For any element $u \in \mathbb{R}^n$, u is n -vector.*

See that the solution set of a linear system (Definition 5) must be a subset of the Euclidean space.

Exercise 30 (Expressions for Geometric Objects in the Euclidean Space). *We show implicit and explicit expressions for objects in low dimensional spaces.*

1. See that a line in \mathbb{R}^2 may be represented (implicitly) by the set notation

$$\{(x, y) | ax + by = c\}, \quad (135)$$

where $a, b, c \in \mathbb{R}$, and it is not the case that both a, b are zero. This may (explicitly) also be written as

$$\left\{ \left(\frac{c - bt}{a}, t \right) \mid t \in \mathbb{R} \right\} \quad \text{if } a \neq 0, \text{ or equivalently} \quad (136)$$

$$\left\{ \left(t, \frac{c - at}{b} \right) \mid t \in \mathbb{R} \right\} \quad \text{if } b \neq 0. \quad (137)$$

2. A plane in \mathbb{R}^3 may be expressed

$$\{(x, y, z) | ax + by + cz = d\} \quad (138)$$

where $a, b, c \in \mathbb{R}$ not all zero and $d \in \mathbb{R}$. We may also write explicitly as any of the equivalent forms

$$\left\{ \left(\frac{d - bs - ct}{a}, s, t \right) \mid s, t \in \mathbb{R} \right\} \quad a \neq 0, \quad (139)$$

$$\left\{ \left(s, \frac{d - as - ct}{b}, t \right) \mid s, t \in \mathbb{R} \right\} \quad b \neq 0, \quad (140)$$

$$\left\{ \left(s, t, \frac{d - as - bt}{c} \right) \mid s, t \in \mathbb{R} \right\} \quad c \neq 0. \quad (141)$$

3. A line in \mathbb{R}^3 may be represented by the explicit set notation

$$\{(a_0 + at, b_0 + bt, c_0 + ct | t \in \mathbb{R}\} = \{(a_0, b_0, c_0) + t(a, b, c) | t \in \mathbb{R}\}, \quad (142)$$

where $a, b, c, a_0, b_0, c_0 \in \mathbb{R}$, and not all a, b, c are zero.

Definition 45 (Set Cardinality). For finite set S , the number of elements in the set (cardinality) is denoted $|S|$.

3.1.3.2 Linear Spans

Definition 46 (Linear Combination). Let $u_i, i \in [k]$ be vectors in \mathbb{R}^n , then $\forall c_i \in \mathbb{R}, i \in [k]$, the vector

$$\sum_i^k c_i u_i \quad (143)$$

is said to be linear combination of the vectors $u_i, i \in [k]$.

Definition 47 (e_i). Denote vectors $e_i \in \mathbb{R}^n$, as the vectors with 1 in the i -th entry and zero everywhere else. That is

$$e_i = (0 \cdots 0 \underbrace{1}_{i\text{-th}} 0 \cdots 0). \quad (144)$$

See that for $u \in \mathbb{R}^n$, we can write $u = \sum_i^n u_i e_i$.

Definition 48 (Linear Span). Let $S = \{u_i, i \in [k]\}$ be set of vectors in \mathbb{R}^n , then the set of all linear combinations of $u_i, i \in [k]$, that is

$$\left\{ \sum_i^k c_i u_i \mid \forall i \in [k], c_i \in \mathbb{R} \right\} \quad (145)$$

is called the linear span of set S and is denoted as $\text{span}(S)$ or $\text{span}\{u_1, \dots, u_k\}$.

See that we may express spans in different ways. For instance, a set $V = \{(2a + b, a, 3b - a) \mid a, b \in \mathbb{R}\}$ can be written as $\text{span}\{(2, 1, -1), (1, 0, 3)\}$.

Exercise 31. Show that

$$V = \text{span}\{(1, 0, 1), (1, 1, 0), (0, 1, 1)\} = \mathbb{R}^3. \quad (146)$$

Proof. $V = \mathbb{R}^3$ if we may write arbitrary vector (x, y, z) as a linear combination of elements in the spanning set of V (we formally define this later, but treat this for now to be the three vectors given). That is, $\exists a, b, c$ s.t.

$$a(1, 0, 1) + b(1, 1, 0) + c(0, 1, 1) = (x, y, z), \quad (147)$$

and this corresponds to augmented matrix system

$$\left[\begin{array}{ccc|c} 1 & 1 & 0 & x \\ 0 & 1 & 1 & y \\ 1 & 0 & 1 & z \end{array} \right] \xrightarrow{\text{GE (Def. 5)}} \left[\begin{array}{ccc|c} 1 & 1 & 0 & x \\ 0 & 1 & 1 & y \\ 0 & 0 & 2 & z - x + y \end{array} \right]. \quad (148)$$

This system is consistent regardless of the values of x, y, z . On the other hand, supposed we performed Gaussian Elimination and obtain zero row on the LHS, that is the coefficient matrix. Then, it is possible for the last column to be a pivot column and for the system to be inconsistent (Result 2). \square

We may generalize Exercise 31 to a more general question of whether a set of vectors span the entire Euclidean space \mathbb{R}^n .

Corollary 2. For set $S = \{u_i, i \in [k]\} \in \mathbb{R}^n$, S spans \mathbb{R}^n iff for arbitrary vector $v \in \mathbb{R}^n$, the linear system represented by the augmented matrix (Definition 9) is consistent, where $(A|v)$ and A is coefficient matrix created from horizontally stacking the column vectors $u_i, i \in [k]$. This is immediately made obvious if we consider the discussion inside the matrix representation for linear systems in Definition 33. By Theorem 2, if $REF(A)$ has no zero row, then the linear system is always consistent. Otherwise, the system is not always consistent and $span(S) \neq \mathbb{R}^n$.

Theorem 26 (Cardinality of a Set and Its Spanning Limitations). For set $S = \{u_i, i \in [k]\}$ be set of vectors in \mathbb{R}^n , if $k < n$, then S cannot span \mathbb{R}^n .

Proof. Since the coefficient matrix obtained from stacking k columns is size $n \times k$, then the result follows directly from Theorem 26. \square

Theorem 27 (Zero Vector and Span Closure). Let $S = \{u_i, i \in [k]\} \subseteq \mathbb{R}^n$. Then,

1. $0 \in span(S)$.
2. For any $v_i \in span(S)$ and $c_i \in \mathbb{R}, i \in [r], \sum_i^r c_i v_i \in span(S)$.

Proof. -

1. See that $0 = \sum_i 0u_i \in span(S)$.
2. For each $v \in span(S)$, they are linear combination of $u_i, i \in [k]$. Then we may express

$$v_1 = a_{11}u_1 + \cdots + a_{1k}u_k, \quad (149)$$

$$v_2 = a_{21}u_1 + \cdots + a_{2k}u_k, \quad (150)$$

$$\cdots \quad (151)$$

$$v_r = a_{r1}u_1 + \cdots + a_{rk}u_k, \quad (152)$$

$$(153)$$

so that for linear combination

$$c_1v_1 + \cdots + c_rv_r = (c_1a_{11} + c_2a_{21} + \cdots + c_ra_{r1})u_1 \quad (154)$$

$$+ (c_1a_{12} + c_2a_{22} + \cdots + c_ra_{r2})u_2 \quad (155)$$

$$+ \cdots \quad (156)$$

$$+ (c_1a_{1k} + c_2a_{2k} + \cdots + c_ra_{rk})u_k. \quad (157)$$

See this is in $span(S)$. \square

Theorem 28 (Spanning Set of a Set Span). For $S_1 = \{u_i, i \in [k]\}, S_2 = \{v_j, j \in [m]\} \subseteq \mathbb{R}^n$, $span(S_1) \subseteq span(S_2)$ iff for all $i \in [k]$, u_i is a linear combination of $v_j, j \in [m]$.

Proof. \rightarrow : Assume $span(S_1) \subseteq span(S_2)$, then since $S_1 \subseteq span(S_1) \subseteq span(S_2)$, each u_i is linear combination of v 's.

\leftarrow : Assume $\forall i \in [k], u_i$ is linear combination of v 's. Then, $u_i \in span(S_2), \forall i \in [k]$. By Theorem 27, any w that is linear combination of these u 's can rewritten as linear combination of the v 's, which is itself in $span(S_2)$. Then we are done. \square

Exercise 32. Discuss how one may approach to see if for some set S_1, S_2 , whether $\text{span}(S_1) \subseteq \text{span}(S_2)$.

Proof. Let the vectors in S_1 be denoted $u_i, i \in [n]$ and in S_2 be denoted $v_j, j \in [m]$. Then in order to see if each u_i may be represented as a linear combination of the v_j 's, we may simultaneously solve for multiple linear systems. These linear systems may be represented by an augmented matrix $(V|u_1|u_2 \cdots |u_k)$, and by Gaussian Elimination we are able to check if any of the systems $(V|u_i), i \in [n]$ are not consistent. V here is obtained by horizontally stacking the column vectors for v_i . This follows from the discussion made in Definition 33 on constant matrix as linear combinations of the columns in the coefficient matrix. \square

Theorem 29 (Redundant Vectors). Let $S = \{u_i, i \in [k]\} \subseteq \mathbb{R}^n$, and if $\exists j \in [k]$ s.t. u_j is linear combination of vectors in $S \setminus u_j$, then $\text{span}(S) = \text{span}(S \setminus u_j)$.

Proof. The proof follows directly from applying Theorem 28. \square

Let u, v be two nonzero vectors. Then $\text{span}\{u, v\} = su + tv, \forall s, t \in \mathbb{R}$. If it is not the case that $u//v$, then $\text{span}\{u, v\}$ is a plane containing origin. In \mathbb{R}^2 space, the span is just the entire space. In \mathbb{R}^3 , the span can be written

$$\text{span}\{u, v\} = \{su + tv | s, t \in \mathbb{R}\} = \{(x, y, z) | ax + by + cz = 0\}, \quad (158)$$

where (a, b, c) is solution to the system of two linear equations $u_1a + u_2b + u_3c = 0, v_1a + v_2b + v_3c = 0$ for $u = (u_1, u_2, u_3), v = (v_1, v_2, v_3)$.

For a line in $\mathbb{R}^2, \mathbb{R}^3$, see that any point on the line may be represented by a point x plus some vector u that is scaled. That is, the line may be written by some

$$L = \{x + tu | t \in \mathbb{R}\} \quad (159)$$

$$= \{x + w | w \in \text{span}(u)\}. \quad (160)$$

On the other hand, for some plane in \mathbb{R}^3 , and u non-parallel to v , we may represent plane

$$P = \{x + su + tv | s, t \in \mathbb{R}\} \quad (161)$$

$$= \{x + w | w \in \text{span}\{u, v\}\}. \quad (162)$$

A generalization of this statement can be made in \mathbb{R}^n . That is,

1. for $x, u \in \mathbb{R}^n, u \neq 0$, the set

$$L = \{x + w | w \in \text{span}\{u\}\} \quad (163)$$

is a line in \mathbb{R}^n .

2. For $x, u, v \in \mathbb{R}^n, u \cdot v \neq 0$, and $u \neq kv$ for some $k \in \mathbb{R}$, then the set

$$P = \{x + w | w \in \text{span}\{u, v\}\} \quad (164)$$

is plane in \mathbb{R}^n .

3. Take $x, u_1, u_2, \dots, u_r \in \mathbb{R}^n$ the set

$$Q = \{x + w | w \in \text{span}\{u_1, \dots, u_r\}\} \quad (165)$$

is a k -plane in \mathbb{R}^n where k is the dimension of the $\text{span}\{u_1, \dots, u_r\}$. Dimensions of vector spaces are introduced in Section 3.1.3.6.

3.1.3.3 Subspaces

Definition 49 (Subspace). For $V \subseteq \mathbb{R}^n$, V is subspace of \mathbb{R}^n if $V = \text{span}(S)$, $S = \{u_1, \dots, u_k\}$ for some vectors $u_{i \in [k]} \in \mathbb{R}^n$. We say that V is the subspace spanned by S . We say that S spans V . We say that u_1, u_2, \dots, u_k span V . We say that S is the spanning set for V .

Definition 50 (Zero Space). From Definition 49 and Theorem 27, see that $0 \in \mathbb{R}^n$ spans the subspace that contains itself, that is $\text{span}\{0\} = \{0\}$. This is known as the zero space.

Recall the vectors e_i 's defined as in (Definition 47). For vectors $e_i, i \in [n] \in \mathbb{R}^n$, see that for all $u = (u_1, \dots, u_n) \in \mathbb{R}^n$, we may write $u = \sum_i^n u_i e_i$, so it follows that $\mathbb{R}^n = \text{span}(\{e_1, \dots, e_n\})$. Trivially, \mathbb{R}^n is subspace of itself. In abstract linear algebra texts, the definition of subspace is relaxed to permit abstract objects and are usually provided as follows (see that Theorem 27 holds under this definition):

Definition 51 (Subspace). Let V be non-empty subset of \mathbb{R}^n . Then V is subspace of \mathbb{R}^n iff

$$\forall u, v \in V, \forall c, d \in \mathbb{R}, \quad cu + dv \in V. \quad (166)$$

Theorem 30 (HLS Solution Space). The solution set of a HLS (Definition 18) in n variables is subspace of \mathbb{R}^n . We call this the solution space of the HLS.

Proof. Let the matrix representation of the HLS be $Ax = 0$. If the HLS only has trivial solution, then the solution space is spanned by the trivial solution and is the zero space. Next, if it has non-trivial solution, then it has infinitely many solutions (see Lemma 2). Then by Definition 33, we may let solutions $x = \sum_i^{n_{\text{cols}}(A)} a_i$ where a_i is column vector of the coefficient matrix A . That is, the solution space is spanned by the columns of A , and is therefore subspace of \mathbb{R}^n . \square

If we solve some linear system and arrive at the general solution, it is easy to find the spanning vectors. For instance, let the general solution be

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 2s - 3t \\ s \\ t \end{pmatrix} = s \begin{pmatrix} 2 \\ 1 \\ 0 \end{pmatrix} + t \begin{pmatrix} -3 \\ 0 \\ 1 \end{pmatrix}. \quad (167)$$

The solution space is therefore $\{(2s - 3t, s, t) \mid s, t \in \mathbb{R}\} = \text{span}\{(2, 1, 0), (-3, 0, 1)\}$.

3.1.3.4 Linear Independence

We saw the concept of vector redundancy in a spanning set in Theorem 29. Here, we give formal treatment to such vectors with the concept of linear independence.

Definition 52 (Linear (In)Dependence). For set $S = \{u_i, i \in [k]\} \in \mathbb{R}^n$, consider $\sum_i^k c_i u_i = 0$, for $c_i \in \mathbb{R}, i \in [k]$. This has a HLS representation (Definition 18) where the coefficient matrix U is obtained

from stacking the vectors horizontally, s.t $U = \begin{pmatrix} u_1 & \dots & u_k \end{pmatrix}$ and $c = \begin{pmatrix} c_1 \\ \dots \\ c_k \end{pmatrix}$ is the variable matrix.

Then see that the zero solution satisfies the system always. The set S is said to be linearly independent and u_1, \dots, u_k are said to be linearly independent if the HLS only has the trivial solution. Otherwise, $\exists a_{i \in [k]} \neq 0$ and $\sum_i^k a_i u_i = 0$; a non-trivial solution exists. Then S is a linearly dependent set and u_1, \dots, u_k are said to be linearly dependent vectors. For brevity, we use the notations

$$LIND(S) = LIND\{u_1, u_2, \dots, u_k\} \quad (168)$$

to indicate linear independence and

$$\neg LIND(S) = \neg LIND\{u_1, u_2, \dots, u_k\} \quad (169)$$

to indicate linear dependence.

Let $S = \{u\}$ be a subset of \mathbb{R}^n , then S is linearly dependent iff $u = 0$. For $S = \{u, v\} \subset \mathbb{R}^n$, S is linearly dependent iff $u = av$, for some $a \in \mathbb{R}$. If $0 \in S$ for arbitrary $S \in \mathbb{R}^n$, it must be linearly dependent.

Theorem 31 (No Redundancy of Linearly Independent Set). *Let $S = \{u_i, i \in [k]\} \subset \mathbb{R}^n$ where $k \geq 2$. Then, S is linearly dependent iff $\exists i \in [k]$ s.t. u_i is a linear combination of vectors in $S \setminus u_i$. Equivalent statement by the iff condition is that S is linearly independent iff no vector in S may be written as linear combination of the other vectors.*

Proof. \rightarrow : If $LIND(S)$, then $\sum_i^n a_i u_i = 0$ has non-trivial solution by Definition 52. Without loss of generality, let $a_i \neq 0$, then

$$u_i = -\frac{a_1}{a_i} u_1 - \frac{a_2}{a_i} u_2 - \dots - \frac{a_{i-1}}{a_i} u_{i-1} - \frac{a_{i+1}}{a_i} u_{i+1} - \dots - \frac{a_k}{a_i} u_k. \quad (170)$$

We have showed directly that u_i is l.c of the other vectors. \leftarrow : If $\exists u_i = \sum_{j \neq i}^k a_j u_j$, for some real numbers $a_j \in [k], j \neq i$. Then let $a_i = -1$, for which we have

$$a_1 u_1 + \dots + a_{i-1} u_{i-1} + a_i u_i + a_{i+1} u_{i+1} + \dots + a_k u_k \quad (171)$$

$$= u_i - u_i \quad (172)$$

$$= 0. \quad (173)$$

So we have found some non-zero solution, and hence by definition, S must be linearly dependent. \square

Recall Theorem 26 on the minimum size of a spanning set required for \mathbb{R}^n . Here we give statements that allow us to determine the maximum size of the spanning set for \mathbb{R}^n that is linearly independent.

Theorem 32. *Let $S = \{u_i, i \in [k]\} \in \mathbb{R}^n$. If $k > n$, then S is linearly dependent.*

Proof. The proof follows immediately by seeing that the HLS representation by stacking columns of u has non-trivial solutions by Lemma 2. S is linearly dependent by Definition 52 as a result. \square

Theorem 33 (No Redundancy of Non-Linearly Combinable Element). *Let $u_i, i \in [k]$ be linearly independent vectors in \mathbb{R}^n . If $u_{k+1} \in \mathbb{R}^n$, and it is not l.c. of $u_i, i \in [k]$, then $\{u_i, i \in [k]\} \cup \{u_{k+1}\}$ is linearly independent.*

Proof. We show that the vector equation

$$\sum_i^{k+1} c_i u_i = 0 \quad (174)$$

has only trivial solution. See that $c_i, i \in [k]$ must be zero by itself in the HLS in k variables by assumption and definition for linear independence (Definition 52). We just need to show that $c_{k+1} = 0$. Suppose not, then we may write

$$u_{k+1} = -\sum_{i=1}^k \frac{c_i}{c_{k+1}} u_i \quad (175)$$

and this is a contradiction since we assumed no linear combination is possible. So, c_{k+1} must be zero. Therefore, the HLS represented for $u_i, i \in [k+1]$ must have only the trivial solution. \square

3.1.3.5 Bases

Definition 53 (Vector Spaces and Subspaces of Vector Space). *A set V is vector space if either $V = \mathbb{R}^n$ or V is subspace (Definition 49, 51) of \mathbb{R}^n for some $n \in \mathbb{Z}^+$. For some vector space W , the set S is subspace of W if S is a vector space contained inside W .*

We may be interested in finding the smallest set possible s.t. all vector in some vector space V may be represented as a linear combination of the elements in the set.

Definition 54 (Basis). *Let $S = \{u_1, u_2, \dots, u_k\}$ be subset of a vector space V (Definition 53). Then we say that S is a basis for V if (i) S is linearly independent (Definition 52) and (ii) S spans V (Definition 48). When $V = \{0\}$, the zero space, set \emptyset to be the basis.*

That is, a basis for a vector space V must contain the smallest possible number of elements that can span V , since it must have no redundant vectors. Recall from Theorem 28 that for vector space V spanned by some set S , if all elements in S may be represented by some linear combination of vectors in \tilde{S} , and \tilde{S} is linearly independent, then \tilde{S} must be basis for $\text{span}(S) = V$ by definition of basis (Definition 54).

Theorem 34 (Unique Representation of Elements on Basis). *If $S = \{u_i, i \in [k]\}$ is basis for vector space V , then $\forall v \in V$, v has unique representation $v = \sum_i^k c_i u_i$.*

Proof. Suppose $\exists c_i \in [k], d_j \in [k]$ s.t. $v = \sum_{i=1}^k c_i u_i = \sum_{j=1}^k d_j u_j$, then by subtracting the two equations, get

$$(c_1 - d_1)u_1 + (c_2 - d_2)u_2 + \dots + (c_k - d_k)u_k = 0. \quad (176)$$

But since S is linearly independent (it is basis), the only solution is the trivial solution, so $\forall i \in [k], c_i = d_i$. \square

By Theorem 34, we should be able to specify an arbitrary vector in some vector space w.r.t to the coefficients of the l.c. on its basis.

Definition 55 (Basis Coordinates). *Let $S = \{u_i, i \in [k]\}$ be basis for a vector space V and $v \in V$, then since v may uniquely expressed by some $c_i, i \in [k]$ (by Theorem 34) as $v = \sum_i^k c_i u_i$, we say that the coefficients c_i are coordinates of v relative to basis S and call the vector $(v)_S = (c_1, c_2, \dots, c_k) \in \mathbb{R}^k$ the coordinate vector of v relative to basis S .*

To find the coordinate vector of some v relative to some basis S , we may simply solve for the linear system $\tilde{S}x = v$, where \tilde{S} is coefficient matrix obtained by stacking the column vectors of elements of S . We give formal definition for a collection of vectors that we denoted e_i (Definition 47).

Definition 56 (Standard Basis). *Let $E = \{e_i, i \in [n]\}$ where e_i is the vector of all zeros, except for a single entry of one in the i th-coordinate. Then it is easy to see that E spans \mathbb{R}^n , and that $LIND(E)$. E is basis for \mathbb{R}^n . In particular, we call this the standard basis, and see that*

$$(u)_E = (u_1, \dots, u_n) = u. \quad (177)$$

Corollary 3. *By Definition 55, for basis S of V , $\forall u, v \in V$, $u = v$ iff $(u)_S = (v)_S$. Additionally, by Definition 55, $\forall v_i \in [r] \in V$, $c_i \in [r] \in \mathbb{R}$, see that*

$$(c_1 v_1 + c_2 v_2 + \dots + c_r v_r)_S = c_1 (v_1)_S + c_2 (v_2)_S + \dots + c_r (v_r)_S. \quad (178)$$

Theorem 35 (Linear Dependence Duality). *Let S be basis for vector space V (Definition 54, 53), and $|S| = k$. Let $v_i \in V, i \in [r]$, then*

1. $LIND(\{v_i, i \in [r]\}) \leftrightarrow LIND(\{(v_i)_S, i \in [r]\})$ for vectors $(v_i)_S \in \mathbb{R}^k$.
2. $span\{v_i, i \in [r]\} = V$ iff $span\{(v_i)_S, i \in [r]\} = \mathbb{R}^k$.

Proof. -

1. By Corollary 3, we can write $\sum_i^r c_i v_i = 0 \leftrightarrow (\sum_i^r c_i v_i)_S = (0)_S \leftrightarrow \sum_i^r c_i (v_i)_S = (0)_S$, where $(0)_S \in \mathbb{R}^k$. The first equality has non-trivial solution iff the last equality has the non-trivial solution and we are done.
2. Assume $S = \{u_i, i \in [k]\}$. \rightarrow : Assume $span\{v_i, i \in [r]\} = V$. Then by closure (Theorem 27) and basis definitions (Definition 54), we may write

$$\forall a = (a_1, \dots, a_k) \in \mathbb{R}^k, \quad w := \sum_i^k a_i u_i \in V = \sum_j^r c_j v_j \quad (179)$$

for some constants $c_j, j \in [r]$. By basis coordinate (Definition 55) and Corollary 3, we may write

$$a = (w)_S = (c_1 v_1 + \dots + c_r v_r)_S = c_1 (v_1)_S + \dots + c_r (v_r)_S. \quad (180)$$

Then it follows that $(v_i)_S, i \in [r]$ spans \mathbb{R}^k . \leftarrow : On the other hand, suppose $span\{(v_i)_S, i \in [r]\} = \mathbb{R}^k$. See that $\forall w \in V, (w)_S \in \mathbb{R}^k$ so $\exists c_i, i \in [r]$ s.t.

$$(w)_S = \sum_i^r c_i (v_i)_S = (\sum_i^r c_i v_i)_S, \quad (181)$$

and therefore $w = \sum_i^r c_i v_i$ by Corollary 3. Since we picked arbitrary w , we are done. □

3.1.3.6 Dimensions

Theorems 26 and 32 give statements of the number of elements required for a basis for a vector space that is \mathbb{R}^k - here we use the duality given by Theorem 35 to make comments on arbitrary real vector space V .

Theorem 36 (Vector space has fixed size basis). *Let V be vector space with basis $S, |S| = k$. Then*

1. *Any subset of V with more than k vectors is always linearly dependent, and*
2. *Any subset of V with less than k vectors cannot span V .*

Proof. -

1. Let $T = \{v_i, i \in [r]\} \subset V$, and $r > k$. Then their coordinate vectors $(v_i)_S$ are set of r vectors in \mathbb{R}^k , and since $r > k$, by Theorem 32, $(v_i)_S, i \in [r]$ is linearly dependent, then by duality (Theorem 35) it follows that $\neg LIND(T)$.
2. Let $Q = \{v_i, i \in [t]\} \subset V$ and $t < k$, then $(v_i)_S, i \in [t]$ may not span \mathbb{R}^k (Theorem 26) and Q cannot span V by duality (Theorem 35).

□

Theorem 36 gives us a metric for the ‘size’ of a vector space. We formalize this with dimensions.

Definition 57 (Dimensions, \dim). *The dimension of a vector space V , denoted $\dim(V)$ is the number of vectors in any basis for V . Since zero space has basis \emptyset (Definition 54), $\dim(0) = 0$.*

We can see that the dimension of a vector space denote the concept of degrees of freedom. Consider the subspace $W = \{(x, y, z) | y = z\}$. We may write $\forall w \in W, w := (x, y, y) = x(1, 0, 0) + y(0, 1, 1)$, s.t. $W = \text{span}\{(1, 0, 0), (0, 1, 1)\}$. Additionally, $(1, 0, 0), (0, 1, 1)$ are linearly independent and so they form basis. $\dim(W) = 2$.

Exercise 33 (Finding the Nullity and Basis of a HLS Solution Space). *By considering the (R)REF of an HLS (Definition 18), it is easy to see that the dimension of the solution space is the number of non-pivot columns (Definition 16) in the (R)REF form. To see this, suppose that the RREF representation of some HLS in variables (v, w, x, y, z) may be written to be*

$$\left[\begin{array}{ccccc|c} 1 & 1 & 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{array} \right], \quad (182)$$

then by back substitution (Exercise 4), see that the linear system may have general solution

$$\begin{pmatrix} v \\ w \\ x \\ y \\ z \end{pmatrix} = \begin{pmatrix} -s - t \\ s \\ -t \\ 0 \\ t \end{pmatrix} = s \begin{pmatrix} -1 \\ 1 \\ 0 \\ 0 \\ 0 \end{pmatrix} + t \begin{pmatrix} -1 \\ 0 \\ -1 \\ 0 \\ 1 \end{pmatrix} \quad (183)$$

for $s, t \in \mathbb{R}$. Then see that the dimension of the solution space is 2, and in fact we found the basis for the solution space $\{(-1, 1, 0, 0, 0), (-1, 0, -1, 0, 1)\}$. This solution space is known as the nullspace, and we have found the basis of the nullspace. The cardinality of this basis is known as the nullity. The nullspace, basis, and nullity are discussed later in Definition 64, Definition 54 and Definition 65 respectively.

Theorem 37. *Let V be vector space, dimension k (Definition 57) and $S \subset V$. The statements are equivalent for:*

1. S is basis for V .
2. $\text{LIND}(S) \wedge |S| = k$.
3. S spans V and $|S| = k$.

That is, if we know $|S| = k$, we only need to check if $\text{span}(S) = V$ or $\text{LIND}(S)$ to show it is basis for V .

Proof. The statements for $1 \rightarrow 2, 1 \rightarrow 3$ follow from Theorem 36. Additionally, to show $2 \rightarrow 1$, assume S is linearly independent and $|S| = k$. Suppose it is not basis for V , then take the vector $u \in V \wedge u \notin \text{span}(S)$. Then by Theorem 31, $S' = S \cup \{u\}$ is set of $k + 1$ linearly independent vectors, and Theorem 36 asserts the contradiction. To show $3 \rightarrow 1$, assume S spans V , $|S| = k$ and suppose S is not basis. Then $\exists v \in S$ s.t. $v = \sum_{s_i \in S \setminus v} c_i s_i$ for some constants $c_i \in \mathbb{R}$, and $\tilde{S} := S \setminus v$ is set of $k - 1$ vectors where $\text{span}(\tilde{S}) = \text{span}(S) = V$ by Theorem 29. Theorem 36 asserts the contradiction. □

Theorem 38 (Dimension of a Subspace). *Let U be subspace (Definition 49) of vector space V . Then $\dim(U) \leq \dim(V)$. In particular, $U \neq V \implies \dim(U) < \dim(V)$.*

Proof. Let S be basis for U , so $S \subseteq U \subseteq V$ and since it is basis, S is linearly independent subset of V . By part 1, Theorem 36, since S is linearly independent, it must not have more than $k = \dim(V)$ vectors, that is $\dim(U) = |S| \leq \dim(V)$. On the other hand, assume $|S| = \dim(U) = \dim(V)$, then Theorem 37 asserts that the linear independence of S and set cardinality makes $V = \text{span}(S) = U$. So we have shown that

$$\dim(U) = \dim(V) \implies U = V \quad (184)$$

Since $(\dim(U) \leq \dim(V)) \wedge (\dim(U) \geq \dim(V)) \leftrightarrow \dim(U) = \dim(V)$, we have effectively showed the contrapositive of the statement, and by logical equivalency we are done. \square

Theorem 39 (Invertibility of Square Matrices, 2). *If A is square matrix order n , then the following statements are equivalent:*

1. A is invertible.
2. $Ax = 0$ has only the trivial solution.
3. RREF of A is identity $\mathbb{1}$ matrix.
4. A can be expressed as $\prod_i^n E_i$, where E_i are elementary matrices.
5. $\det(A) \neq 0$.
6. Rows of A form basis for \mathbb{R}^n .
7. Columns of A form basis for \mathbb{R}^n .

Proof. See proof in Theorem 11 for the iff conditions for statement $1 \leftrightarrow 4$. $1 \leftrightarrow 5$ is proved by Theorem 21. $6 \leftrightarrow 7$ by Theorem 10 - rows of A are columns of A' and A invertible iff A' is invertible. We are done if we show any $i \in [5] \leftrightarrow 7$. We show $2 \leftrightarrow 7$. If $Ax = 0$ only has trivial solution, then the columns are linearly independent by the statements given in Definition 52. There are n columns. Then by Theorem 37, $\{a_1, a_2, \dots, a_n\}$ where a_i is i -th column of A is basis of \mathbb{R}^n . \square

3.1.3.7 Transition Matrices

Definition 58 (Row/Column Vector Representation of Basis Coordinates). *Recall that for basis $S = \{u_i, i \in [k]\}$ of vector space V and $v \in V$, v has unique coordinate vector representation (Definition 55, Theorem 34) written*

$$(v)_S = (c_1, \dots, c_k) \quad (185)$$

and we write also write this as a column vector

$$[v]_S = \begin{pmatrix} c_1 \\ c_2 \\ \dots \\ c_k \end{pmatrix}. \quad (186)$$

It is trivial that bases are not unique. For two bases S, T spanning vector space V , we may be interested in the relation $[w]_S \sim [w]_T$. This relation is captured by the transition matrix. In particular,

let $S = \{u_i, i \in [k]\}, T = \{v_i, i \in [k]\}$ and some $w \in V$ be written $w = \sum c_i u_i$ s.t. $[w]_S = \begin{pmatrix} c_1 \\ c_2 \\ \dots \\ c_k \end{pmatrix}$, then

since each u_i 's may be represented by the vectors in T , suppose

$$\forall i \in [k], \quad u_i = a_{1i}v_1 + a_{2i}v_2 + \dots + a_{ki}v_k. \quad (187)$$

That is, each $u_i \in [k]$ has T -basis coordinate representation $[u_i]_T = \begin{pmatrix} a_{1i} \\ a_{2i} \\ \dots \\ a_{ki} \end{pmatrix}$ and see that

$$w = \sum_j^k (c_1 a_{j1} + c_2 a_{j2} + \dots + c_k a_{jk}) v_j. \quad (188)$$

That is,

$$[w]_T = \begin{pmatrix} c_1 a_{11} + c_2 a_{12} + \dots + c_k a_{1k} \\ c_1 a_{21} + c_2 a_{22} + \dots + c_k a_{2k} \\ \dots \\ c_1 a_{k1} + c_2 a_{k2} + \dots + c_k a_{kk} \end{pmatrix} = \begin{pmatrix} [u_1]_T & [u_2]_T & \dots & [u_k]_T \end{pmatrix} [w]_S. \quad (189)$$

Define $P = \begin{pmatrix} [u_1]_T & [u_2]_T & \dots & [u_k]_T \end{pmatrix}$, then $[w]_T = P[w]_S$ for all $w \in V$ and we call P the transition matrix.

Definition 59 (Transition Matrix). *Let $S = \{u_1, \dots, u_k\}$ and T be two bases for vector space. Then $P = ([u_1]_T \dots [u_k]_T)$ is said to be transition matrix from S to T , and $[w]_T = P[w]_S$ holds for all $w \in V$.*

We may find the transition matrix by the Gaussian Elimination (or Gauss Jordan) algorithm discussed in Theorem 5 and using the interpretations for linear systems as in Definition 33. For two bases $S = \{u_i, i \in [k]\}, T = \{v_i, i \in [k]\}$ respectively, we solve for the system with augmented matrix representation (Definition 9) $(T|u_1|u_2 \dots |u_k)$, where T is coefficient matrix obtained from stacking column vectors $v_i, i \in [k]$. Then the column vectors on the RHS of the RREF augmented matrix are the weights for the linearly combined columns of T . In fact, the RHS of the augmented matrix from the first $|$ onwards is precisely the transition matrix $P : [w]_S \rightarrow [w]_T$.

Theorem 40 (Properties of the Transition Matrix). *Let S, T be two bases of vector space V and P be transition matrix from $S \rightarrow T$, then*

1. P is invertible and
2. P^{-1} is the transition matrix from $T \rightarrow S$.

Proof. It is easy to both logicize this argument and to prove it. Note that for $S = \{u_i, i \in [k]\}$, the vectors $[u_i]_S, i \in [k]$ is standard basis (Definition 56) in \mathbb{R}^k . Let Q be transition matrix from T to S . Then see that for $i \in [k]$, the i -th column of QP is written $QP[u_i]_S = Q[u_i]_T = [u_i]_S$. Then stacking the columns $[u_i]_S, i \in [k]$ gives us $\mathbb{1}_k$. \square

Exercise 34. Discuss if the following is true:

1. If S_1, S_2 are finite subsets of \mathbb{R}^n , then $\text{span}(S_1 \cap S_2) = \text{span}(S_1) \cap \text{span}(S_2)$.
2. If S_1, S_2 are finite subsets of \mathbb{R}^n , then $\text{span}(S_1 \cup S_2) = \text{span}(S_1) \cup \text{span}(S_2)$.

Proof. -

1. False, consider the sets $S_1 = \{(1, 0), (0, 1)\}, S_2 = \{(1, 0), (0, 2)\}$.
2. False, consider the sets $S_1 = \{(1, 0)\}, S_2 = \{(0, 1)\}$.

□

Exercise 35 (Coset). Let W be subspace of \mathbb{R}^n and $v \in \mathbb{R}^n$, then

$$W + v = \{u + v \mid u \in W\} \quad (190)$$

is said to be coset of W containing v . Give geometric interpretations for the coset $W + v$ when

1. $W = \{(x, y) \mid x + y = 0\}, v = (1, 1)$.
2. $W = \{(c, c, c) \mid c \in \mathbb{R}\}, v = (0, 0, 1)$.
3. $W = \{(x, y, z) \mid x + y + z = 0\}, v = (2, 0, -1)$.

Proof. -

1. The line $x + y = 2$ in \mathbb{R}^2 .
2. The line $\{(0, 0, 1) + c(1, 1, 1) \mid c \in \mathbb{R}\}$ in \mathbb{R}^3 .
3. The plane $x + y + z = 1$ in \mathbb{R}^3 .

□

The union of subspaces are rarely a subspace; we define sums of subspaces.

Definition 60 (Subset Addition). Suppose $U_i, i \in [m]$ are subsets of V , then we denote the sum of subsets $U_1 + \cdots + U_m$ to be the set of all possible sum of elements $U_i, i \in [m]$, that is

$$\sum_i^m U_i = \left\{ \sum_i^m u_i \mid \forall i \in [m], u_i \in U_i \right\}. \quad (191)$$

Exercise 36. Let V, W be subspaces of \mathbb{R}^n , then show that $V + W$ (see Definition 60) is subspace of \mathbb{R}^n .

Proof. Let $V = \text{span}\{v_i, i \in [m]\}, W = \text{span}\{w_i, i \in [n]\}$, then

$$V + W = \{v + w \mid v \in V, w \in W\} \quad (192)$$

$$= \left\{ \sum a_i v_i + \sum b_j w_j \mid a_i, b_j \in \mathbb{R}, \forall i \in [m], \forall j \in [n] \right\} \quad (193)$$

$$= \text{span}\{v_1, \dots, v_m, w_1, \dots, w_n\}, \quad (194)$$

so $V + W$ is subspace of \mathbb{R}^n .

□

Exercise 37. Let A be $m \times n$ matrix, and $V_A = \{Au \mid u \in \mathbb{R}^n\}$. Show that V_A is subspace of \mathbb{R}^m . Let A be square matrix order n . Show $W_A := \{u \in \mathbb{R}^n \mid Au = u\}$ is subspace of \mathbb{R}^n .

Proof. Let $A = (c_1 \cdots c_n)$ be column-stacked representation of A , then $\forall u \in \mathbb{R}^n$, see that $Au = \sum_i^n u_i c_i$, so $V_A = \text{span}\{c_i, i \in [n]\}$ is subspace of \mathbb{R}^n . Next, see that

$$Au = u \leftrightarrow (A - \mathbb{1})u = 0, \quad (195)$$

and since W_A is the solution set of $(A - \mathbb{1})u = 0$, W_A must be subspace of \mathbb{R}^n . In fact, V_A is an instance of a column space and W_A is an instance of a nullspace. These are discussed in (Definition 61 and Definition 64). \square

Exercise 38. Let V, W be subspaces of \mathbb{R}^n . Show that $V \cap W$ is subspace of \mathbb{R}^n . Show $V \cup W$ is subspace of \mathbb{R}^n iff $V \subseteq W$ or $W \subseteq V$.

Proof. Both V, W contain zero, so $V \cap W$ is nonempty. Let u, v be vectors in $V \cap W$ and $a, b \in \mathbb{R}$, then $au + bv$ is in V by span closure (Theorem 27) and $au + bv$ is also in W by the span closure. So it must be in $V \cap W$ and we are done with the first part.

We show the second statement. \leftarrow : suppose $V \subseteq W$, then $V \cup W = W$ and this is subspace of \mathbb{R}^n . Also, if $W \subseteq V$, then $W \cup V = V$ is also subspace of \mathbb{R}^n . \rightarrow Suppose $V \cup W$ is subspace, and suppose that $V \not\subseteq W$. Then $\exists y \in V$ s.t. $y \in V \wedge y \notin W$, and since $V \cup W$ is subspace, for arbitrary $x \in W$, see $x + y \in V \cup W$. It follows that either $x + y \in V$ or $x + y \in W$. Assume it is in W , then $-x \in W$ and writing $(x + y) - x = y \in W$ and this is contradiction. So $x + y \in V$. Since V is subspace, $-y \in V$, $x = (x + y) - y \in V$ and therefore $W \subseteq V$. \square

Exercise 39. Let $u_i, i \in [k]$ be vectors $\in \mathbb{R}^n$, and P be some square matrix order n .

1. Show that $Pu_i, i \in [k]$ linearly independent implies $u_i, i \in [k]$ linearly independent.
2. Show that for linearly independent $u_i, i \in [k]$, $Pu_i, i \in [k]$ linearly independence is guaranteed only if P is invertible.

Proof. -

1. See that

$$\sum_i^k c_i u_i = 0 \implies P\left(\sum_i^k c_i u_i\right) = P0 \implies \sum_i^k c_i P u_i = 0. \quad (196)$$

2. See that

$$\sum_i^k c_i P u_i = 0 \implies P\left(\sum_i^k c_i u_i\right) = 0 \implies \sum_i^k c_i u_i = P^{-1}0 = 0. \quad (197)$$

Each c_i must be zero by linear independence (Definition 52). Verify the last assertion with a counter example using the matrices

$$u_1 = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}, \quad u_2 = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}, \quad P = \begin{pmatrix} 1 & 1 & 0 \\ 1 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad (198)$$

where $Pu_1 = Pu_2$.

\square

Exercise 40. Let $V \in \mathbb{R}^n$, $V \neq \emptyset$. Show V is subspace of \mathbb{R}^n iff $\forall u, v \in V, c, d \in \mathbb{R}, cu + dv \in V$. Show that the largest set of linearly independent vectors in V must span V .

Proof. By Theorem 27, if V is subspace, $\forall u, v \in V, c, d \in \mathbb{R}, cu + dv \in V$. On the other hand, suppose $\forall u, v \in V, cu + dv \in V$ for $c, d \in \mathbb{R}$. We can use this recursively to show that $\forall u_i, i \in [k] \in V, \text{span}\{u_i, i \in [k]\} \subseteq V$. We can show the last statement by contradiction. Suppose not, then $\exists v \in V$ but it is not l.c. of some largest set S of linearly independent vectors. Then $S \cup \{v\}$ is set of linearly independent vector (Theorem 31) and we obtained a larger linearly independent set, a contradiction. \square

Exercise 41. Let V be vector space.

1. Suppose $S \subseteq V$ s.t. $\text{span}(S) = V$. Show $\exists S' \subseteq S$ s.t. S' is basis for V .

2. Suppose $T \subseteq V$ s.t. T is linearly independent, then show $\exists T'$ basis for V s.t. $T \subseteq T'$.

Proof. We show both parts by presenting an algorithm that allows us to obtain precisely the sets specified.

1. $\text{span}(S) = V$, so $|S| \geq n$. If $|S| = n$, then we are done by $S' = S$. Else, S is linearly dependent by (Theorem 36) and $\exists v \in S$ that is l.c. of the remaining vectors; $S' = S \setminus \{v\}$ satisfies $\text{span}(S') = \text{span}(S)$. Repeat until $|S| = n$.

2. $LIND(T)$, so $|T| \leq n$ by Theorem 36. If $|T| = n$ then we are done by Theorem 36. Otherwise, $\exists v \in V$ but $v \notin \text{span}(T)$. Let $T' = T \cup \{v\}$ where T' is linearly independent by Theorem 31. Repeat until $\|T'\| = n$ and we have basis as specified.

\square

Exercise 42. Let V be vector space with $\dim(V) = n$, then show $\exists u_i, i \in [n+1]$ s.t. $\forall v \in V, v$ may be expressed as l.c. of u_i 's with non-negative coefficients.

Proof. Take basis $\{u_i | i \in [n]\}$ spanning V , and write $u_{n+1} = -u_1 - u_2 \cdots - u_n$. Then $\forall v \in V, v = \sum_i^n a_i u_i$ for some $a_i \in \mathbb{R}, i \in [n]$. Define $a := \min\{0, a_1, \dots, a_n\}$, s.t

$$v = (a_1 - a)u_1 + (a_2 - a)u_2 + \cdots + (a_n - a)u_n + (-a)u_{n+1} \quad (199)$$

$$= \sum_i^n a_i u_i + a \sum_i^n (-1)u_i + (-a)u_{n+1}. \quad (200)$$

Each $a_i - a \geq 0, -a \geq 0$ and we are done. \square

Theorem 41 (Subset Addition Bound). Let V, W be subspaces of \mathbb{R}^n . Then,

$$\dim(V + W) = \dim(V) + \dim(W) - \dim(V \cap W). \quad (201)$$

Proof. Let $\{u_i, i \in [k]\}$ be basis spanning $V \cap W$, then by Theorem 41, there $\exists v_i \in V, i \in [m]$ s.t. $\{u_1, \dots, u_k, v_1, \dots, v_m\}$ is basis for V . Also, $\exists w_i, i \in [n]$ s.t. $\{u_1, \dots, u_k, w_1, \dots, w_n\}$ span W . Then see that

$$V + W = \text{span}\{u_i, v_j, w_l, i \in [k], j \in [m], l \in [n]\}. \quad (202)$$

Consider vector equation

$$\sum_i^k a_i u_i + \sum_j^m b_j v_j + \sum_l^n c_l w_l = 0. \quad (203)$$

Since $\sum_l^n c_l w_l = -(\sum_i^k a_i u_i + \sum_j^m b_j v_j) \in V \cap W$, then $\exists d_i \in \mathbb{R}, i \in [k]$ s.t. $\sum_l^n c_l w_l = \sum_i^k d_i u_i$. Then

$$c_1 w_1 + \cdots + c_n w_n - d_1 u_1 - \cdots - d_k u_k = 0, \quad (204)$$

and since the $LIND\{u_i, w_l, i \in [k], l \in [n]\}$ it follows that constants c 's and d 's are all equal to zero. Substitute c 's = 0 into the vector equation to get

$$a_1 u_1 + \cdots + a_k u_k + b_1 v_1 + \cdots + b_m v_m = 0, \quad (205)$$

by $LIND\{u_i, v_j, i \in [k], j \in [m]\}$ it follows that constants a 's and b 's are all zero. So the vector equation has only the trivial solution; the u, v, w 's are all linearly independent. See that we get the relation

$$\dim(V + W) = k + m + n = (k + m) + (k + n) - k = \dim(V) + \dim(W) - \dim(V \cap W). \quad (206)$$

□

Exercise 43. Determine which of these are true.

1. If S_1, S_2 are bases for V, W respectively, where V, W are subspaces of a vector space, then $S_1 \cap S_2$ is basis for $V \cap W$.
2. If S_1, S_2 are bases for V, W respectively, where V, W are subspaces of a vector space, then $S_1 \cup S_2$ is basis for $V + W$.
3. If V, W are subspaces of vector space, then \exists basis S_1 for V and basis S_2 for W s.t. $S_1 \cap S_2$ is basis for $V \cap W$.
4. If V, W are subspaces of vector space, then \exists basis S_1 for V and basis S_2 for W s.t. $S_1 \cup S_2$ is basis for $V + W$.

Proof. -

1. False. Consider $S_1 = \{(1, 0), (0, 1)\}, S_2 = \{(1, 0), (0, 2)\}$.
2. False. Consider $\text{span}\{(1)\}, \text{span}\{(2)\} = \mathbb{R}$.
3. True. These bases are found and reasoned with in the proof for Theorem 41.
4. True. These bases are found and reasoned with in the proof for Theorem 41.

□

3.1.4 Matrix Vector Spaces

Matrices and vector spaces were defined (Definition 19, Definition 53) and we would like to study the vector spaces that are associated with a matrix. In particular, we are interested in the row space, column space and the nullspace of some matrix.

3.1.4.1 Row, Column Spaces

Definition 61 (Row Spaces and Column Spaces). Let $A = (a_{ij})$ be $m \times n$ matrix with columns denoted

(c_1, \dots, c_n) and rows denoted $\begin{pmatrix} r_1 \\ r_2 \\ \dots \\ r_m \end{pmatrix}$ representing A . Then the row space is the subspace of \mathbb{R}^n spanned by $r_i, i \in [m]$, that is $\text{span}\{r_i, i \in [m]\} \subseteq \mathbb{R}^n$. The column space is the subspace of \mathbb{R}^m spanned by $c_i, i \in [n]$, that is $\text{span}\{c_i, i \in [n]\} \subseteq \mathbb{R}^m$. For brevity, we denote the row space and column space associated with matrix A as $\text{rowSpace}(A), \text{colSpace}(A)$ respectively.

It is easy to see that row space A and column space A' are identical, and that column space A and row space A' are identical by definition of transpose (Definition 34).

We have discussed methods to check if some set of vectors are linearly dependent by considering its HLS solution (Definition 52). We want to obtain the basis for row spaces and column spaces respectively. Observe that for matrices A, B with $\text{RREF}(A) = \text{RREF}(B)$, then $A \stackrel{\mathcal{R}}{\equiv} B$.

Theorem 42 (Row Space Invariance Over EROs). Let $A \stackrel{\mathcal{R}}{\equiv} B$, then the row spaces of A, B are identical. That is, the EROs (Definition 10) preserve the row space of a matrix.

Proof. Let $A = \begin{pmatrix} r_1 \\ r_2 \\ \dots \\ r_m \end{pmatrix}$ be m rows for matrix A . The proofs can be obtained by performing the EROs on elements of the set $S = \{r_i, i \in [m]\}$ to obtain \tilde{S} and observing that $\text{span}(S) = \text{span}(\tilde{S})$. For instance, for ERO kr_i , picking some $r_i \in S$ and $\tilde{S} = S \setminus \{r_i\} \cup \{kr_i\}$ preserves the span. We omit the proofs for the other EROs, but they should not be difficult to obtain or reason with. \square

Recall column space A is row space A' , and so column space A has basis formed by taking the non-zero rows in $\text{REF}(A')$. We may employ other methods, however. Note that EROs do not preserve the column space of matrix; consider the simple example of $A \stackrel{\mathcal{R}}{\equiv} B$ where $A = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, B = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and observe they do not share column space.

Theorem 43. Let $A \stackrel{\mathcal{R}}{\equiv} B$, then prove that

1. Set of columns in A is linearly independent iff set of corresponding columns in B is linearly independent.
2. Set of columns in A form basis for $\text{colSpace}(A)$ iff set of corresponding columns in B is basis for $\text{colSpace}(B)$.

Proof. -

1. Let $A = (a_1 \dots a_n)$ be the column stacked representation and B both be $b \times n$ matrices. Assume $A \stackrel{\mathcal{R}}{\equiv} B$ s.t.

$$B = E_k \dots E_1 A. \tag{207}$$

Define $P = E_k \dots E_1$, then $B = PA = (Pa_1 \dots Pa_n)$, and by Theorem 39, P is invertible. By part 1, part 2 of Exercise 39, subset columns a_j 's. $j \in [m], m \leq n$ are linearly independent iff the Pa_j 's are linearly independent.

2. \rightarrow : Suppose some subset of columns S_1 are basis for $\text{colSpace}(A)$. The first part asserts the corresponding columns (say S_2 , where $S_2 = \{Ps | s \in S_1\}$) in B are linearly independent. Clearly, $\text{span}(S_2) \subseteq \text{colSpace}(B)$. So we just need to show that $\text{colSpace}(B) \subseteq \text{span}(S_2)$. Take $u \in \text{colSpace}(B)$, for some real $c_i, i \in [n]$. we have $u = \sum_i^n c_i Pa_i$. Since $\text{span}(S_1) = \text{colSpace}(A)$, then $a_1, \dots, a_n \in \text{span}(S_1)$ and so $Pa_1, \dots, Pa_n \in \text{span}(S_2)$ since the elements of S_2 were obtained by applying P to each element of S_1 . We are done. \square

Theorem 44 (Linear Independence at Pivot Rows and Columns of REF Form). *Proof that the nonzero rows of a matrix and pivot columns of a matrix are linearly independent.*

Proof. That is, we want to prove that pivot rows and pivot columns are linearly independent. First, we show that the pivot rows (nonzero rows) of $\text{REF}(A)$ for some matrix $A_{m \times n}$ is linearly independent. Consider

$$\text{REF}(A) = \begin{pmatrix} r_1 \\ r_2 \\ \dots \\ r_j \\ \dots \end{pmatrix} \quad (208)$$

for j non-zero rows. Each non-zero row has a leading entry (Definition 12). Denote the access operator $[\cdot]$, s.t. $r[l]$ refers to the l -th coordinate of vector r . Then by Definition of REFs (Definition 15), see that each r_i has leading entry to the left of r_j , when $j > i$. For each non-zero row, denote the leading entry for row r_i to be at coordinate l_i , then see that $r_i[l_i] \neq 0$, and $l_j > l_i$ when $j > i$ and $\forall i, j, r_j[l_i] = 0$ when $i < j$. Consider the equation $\sum_i^j c_i r_i = 0$. Suppose $c_1 = 0$, then see that

$$\left(\sum_i^j c_i r_i\right)[l_1] = \sum_i^j c_i (r_i[l_1]) = c_1 r_1[l_1] + c_2 r_2[l_1] + \dots + c_j r_j[l_1] = c_1 r_1[l_1] + 0 \neq 0[l_1]. \quad (209)$$

Therefore, c_1 must be zero. Suppose $c_2 \neq 0$, then

$$\left(\sum_i^j c_i r_i\right)[l_2] = \sum_i^j c_i (r_i[l_2]) = c_1 r_1[l_2] + c_2 r_2[l_2] + \dots + c_j r_j[l_2] = 0 + c_2 r_2[l_2] + 0 \neq 0[l_2]. \quad (210)$$

Repeating this, all $c_i, i \in [j]$ must be equal to zero and we obtain linear independence by Definition 52.

It is easier to prove the linear independence of pivot columns. By Theorem 43, since $\text{REF}(A) \stackrel{\mathbb{R}}{\equiv} \text{RREF}(A)$, if we show linear independence of the $\text{RREF}(A)$ pivot columns, we are done. By definition of Gauss-Jordan elimination (Theorem 5), each pivot column at the $\text{RREF}(A)$ is only non-zero at leading entry and the set of pivot columns have non-zero entry at different coordinates. It is trivial to see that no pivot column can be represented by a linear combination of the other pivot columns, so by Theorem 31, the set of pivot columns are linearly independent. \square

Theorem 45 (Basis for Row Space in the Row-Echelon Form). *Let A be some matrix, then the non-zero rows in $\text{REF}(A)$ is basis for row space A .*

Proof. This follows directly from row space invariance (Theorem 44) over EROs and linear independence of pivot rows by Theorem 44. \square

By Theorem 44, Theorem 43, since matrix $A \stackrel{\mathcal{R}}{\equiv} REF(A)$, the basis for column space of A may be obtained by taking the columns of A corresponding to the pivot columns (Definition 16) in $REF(A)$. If we would like to find the basis containing the original vectors in the set provided, see that we would first stack the column vectors horizontally and use Gaussian Elimination (Theorem 5) and pick the relevant columns from the original matrix. If we row-stacked and took non-zero vectors from the REF, we would obtain a basis but they might be linear transformations of the original vectors. If we are asked to extend

some linearly independent $S = \{s_i, i \in [k]\}$ to basis for some $\mathbb{R}^n, n > k$, we may take $REF \left(\begin{pmatrix} s_1 \\ s_2 \\ \dots \\ s_k \end{pmatrix} \right)$

and add elements of the standard basis $e_i \in \mathbb{R}^n$ (Definition 56), for i corresponding to the non-pivot columns. Choices other than e_i exists; we just need to ensure that the leading entry of the new vector corresponds to the i -th coordinate.

Theorem 46 (Representations of the Column Space). *For $m \times n$ matrix A ,*

$$colSpace(A) = \{Au \mid u \in \mathbb{R}^n\}. \quad (211)$$

Proof. Let $A = (c_1 \ c_2 \ \dots \ c_n)$, where c_i is column i of A , then $\forall u \in \mathbb{R}^n$, see that $A \cdot u = \sum_i^n u_i c_i \in span\{c_1, c_2, \dots, c_n\}$, so $\{Au \mid u \in \mathbb{R}^n\} \subseteq colSpace(A)$. On the other hand, suppose some $b \in colSpace(A)$, then $\exists u_i \in \mathbb{R}, i \in [n]$ s.t. $b = \sum_i^n u_i c_i = Au$. Then $colSpace(A) \subseteq \{Au \mid u \in \mathbb{R}^n\}$. It follows that $colSpace(A) = \{Au \mid u \in \mathbb{R}^n\}$. \square

Theorem 47 (Constant Matrix is Member of the Column Space). *A system of linear equations $Ax = b$ is consistent iff $b \in colSpace(A)$.*

Proof. The proof immediately follows from Theorem 46; a system of linear equations $Ax = b$ must be consistent iff $\exists u \in \mathbb{R}^n$ s.t. $Au = b$. \square

3.1.4.2 Ranks

Theorem 48 (Dimension Equality in Row and Column Spaces).

$$dim(rowSpace(A)) = dim(colSpace(A)). \quad (212)$$

Proof. This follows immediately from Theorem 44 - the $dim(rowSpace(A)) =$ number of non-zero rows in REF of arbitrary matrix = number of pivot columns = $dim(colSpace(A))$. \square

Definition 62 (Matrix Rank). *The rank of a matrix is the dimension of its row space (or column space, Theorem 48). We denote the rank of some matrix A by $rank(A)$.*

Definition 63 (Full Rank). *It is trivial to see that for $m \times n$ matrix A , $rank(A) \leq \min\{m, n\}$. If $rank(A) = \min\{m, n\}$, we say that matrix A is full rank.*

A square matrix A is full rank iff it is invertible.

Theorem 49 (Rank of Matrix Transpose). *Since row space A is columns space A' , $rank(A) = rank(A')$.*

Corollary 4 (Linear System Consistency and Rank of Augmented Matrix). *A linear system (Definition 5) is consistent iff $rank(A) = rank((A|b))$. That is, when the b is not a pivot column.*

Theorem 50 (Rank Bound of Matrix Product). *Let A, B be $m \times n, n \times p$ matrices respectively. Then,*

$$\text{rank}(AB) \leq \min\{\text{rank}(A), \text{rank}(B)\}. \quad (213)$$

Proof. Let $A = (a_1 \ a_2 \ \cdots \ a_n), B = (b_1 \ b_2 \ \cdots \ b_p)$ be their columnwise representations. Then by block multiplication (see Exercise 11), we may write

$$AB = (Ab_1 \ Ab_2 \ \cdots \ Ab_p) \quad (214)$$

as the columnwise representation for their matrix product. By Theorem 46, see that $\forall i \in [p], Ab_i \in \text{colSpace}(A)$ and since $\text{colSpace}(AB) = \text{span}\{Ab_i, i \in [p]\}$ and each Ab_i may be written as a linear combination of the columns in A , then by Theorem 28, $\text{colSpace}(AB) \subseteq \text{colSpace}(A)$. It follows by Theorem 38 that

$$\text{rank}(AB) \leq \text{rank}(A) \quad (215)$$

Equation 215 asserts that $\text{rank}(B'A') \leq \text{rank}(B')$. We may write $\text{rank}(AB) = \text{rank}((AB)') = \text{rank}(B'A') \leq \text{rank}(B') = \text{rank}(B)$. We have proven the equivalent statement $(\text{rank}(AB) \leq \text{rank}(A)) \wedge (\text{rank}(AB) \leq \text{rank}(B))$. \square

3.1.4.3 Nullspaces

Definition 64 (Nullspace). *Let A be $m \times n$ matrix, then the solution space (Definition 30) of linear system $Ax = 0$ is the nullspace of A . We refer to this subspace as $\text{nullSpace}(A)$.*

Definition 65 (Nullity). *Define the nullity of $m \times n$ matrix A as $\text{nullity}(A) := \dim(\text{nullSpace}(A))$. See that since the solution vector $\in \mathbb{R}^n$, then $\text{nullity}(A) \leq n$.*

We have already seen how to find the basis and nullity of the solution space in Exercise 33, where the nullity was two.

Theorem 51 (Rank-Nullity Theorem / Dimension Theorem for Matrices). *Let A be matrix size $m \times n$. Then $\text{rank}(A) + \text{nullity}(A) = n$.*

Proof. Consider the REF form for $(A|0)$. Reason that $\text{rank}(A)$ corresponds to the number of pivot columns in $\text{REF}(A)$ and $\text{nullity}(A)$ corresponds to the number of non-pivot columns in $\text{REF}(A)$. See Definition 16 and Exercise 33 for intuition. \square

Theorem 52 (Representations of the Solution Space). *See Theorem 46 for representations of the column space of some matrix A . Suppose $Ax = b$ has solution v . Then the solution set of the system may be written*

$$M = \{u + v \mid u \in \text{nullSpace}(A)\}. \quad (216)$$

Proof. Suppose v is solution s.t. $Av = b$, then let $Aw = b$ be some solution s.t. $Aw = b$. For $u := w - v$, we may write

$$Au = A(w - v) = Aw - Av = b - b = 0, \quad (217)$$

so $u \in \text{nullSpace}(A)$. It follows that $u + v = w \in M$ and the solution space $\subseteq M$. On the other hand, $\forall w \in M, \exists u \in \text{nullSpace}(A)$ s.t. $w = u + v$ by assumption. See that

$$Aw = A(u + v) = Au + Av = 0 + b = b, \quad (218)$$

so w is solution. $M \subseteq$ the solution space and we are done. \square

Theorem 52 asserts the $Ax = b$ has the unique solution iff $nullSpace(A)$ is the zero space. That is when $(A|0)$ only has trivial solution.

Exercise 44. Let $V = \{(1, 1, 0, 0), (-1, 0, 1, 0)\}$ and $W = \{(-1, 2, 3, 0), (2, -1, 2, -1)\}$ and find the basis for $V + W$.

Proof. We may find the basis for $V + W$ by stacking v_1, v_2, w_1, w_2 into rows of a matrix and taking the non-zero rows of its REF form. \square

Exercise 45. Let A be square matrix order 3 and describe geometrically the solution set of the HLS $Ax = 0$ when $rank(A)$ is zero, one, two and three respectively.

Proof. By rank-nullity theorem, see that $nullity(A) = 3 - rank(A)$. So when $rank(A) = 0$ the $nullspace(A) = \mathbb{R}^3$, when $rank(A) = 1$ the $nullSpace(A)$ is plane through origin, and when $rank(A) = 2$ the $nullSpace(A)$ is line through origin. Finally, when $rank(A) = 3$ then $nullSpace(A)$ is the zero space. \square

Theorem 53. Let B be $m \times n$ matrix. If $\exists n \times m$ matrix C s.t. $BC = \mathbb{1}$, then we say that C is the right inverse of B . Show that $m \times n$ matrix B has right inverse iff $rank(B) = m$.

Proof. By definition, $rank(B) = dim(colSpace(B)) \leq m$ (see Definition 63). Let $\{e_i, i \in [m]\}$ be standard basis for \mathbb{R}^m , then B has right inverse iff $B(u_1 \cdots u_m) = (e_1 \cdots e_m)$ for some $u_i, i \in [m] \in \mathbb{R}^n$ iff systems $Bx = e_i, i \in [m]$ are consistent for all $i \in [m]$ iff $e_i, i \in [m] \in colSpace(B)$ iff $m \leq dim(colSpace(B)) \leq m$ iff $rank(B) = m$. \square

Exercise 46. Suppose A, B are two matrices and $AB = 0$, then show that $colSpace(B) \subseteq nullSpace(A)$.

Proof. Define $B = (b_1 \cdots b_n)$ to be the column stacked representation for B , and see that

$$AB = 0 \implies (Ab_1 \cdots Ab_n) = 0 \implies \forall j \in [n], \quad Ab_j = 0. \quad (219)$$

The result follows. \square

Exercise 47. Prove that no matrix has row space and nullspace that contain the same nonzero vector.

Proof. We show that the only vector that is both in row space and column space must be the zero

vector. Let $A = \begin{pmatrix} a_1 \\ \cdots \\ a_n \end{pmatrix}$ be row-stacked representation for A , and let $u \in nullSpace(A)$. Then see that

$Au = 0 \implies a_i u = 0$ for all i . Suppose $u \in rowSpace(A)$, then $u = \sum_i^n c_i a_i$ for some constants $c_i, i \in [n]$. Then

$$u'u = \sum_i^n c_i a_i u = 0 = \sum_i^n u_i^2 = 0 \leftrightarrow \forall i \in [n] \quad u_i = 0. \quad (220)$$

\square

Theorem 54. Let A, P be $m \times n$ matrix and $m \times m$ matrix respectively. If P is invertible, then show that $rank(PA) = rank(A)$. If $rank(PA) = rank(A)$, does this imply P is invertible?

Proof. Since P is invertible, by Theorem 39, P is product of elementary matrices, say $\Pi_i^n E_i$. Then $PA = \Pi_i^n E_i A$, and $P \stackrel{\mathcal{R}}{\equiv} A$, and by Theorem 42, they share row space. Then

$$\text{rank}(PA) = \dim(\text{rowSpace}(PA)) = \dim(\text{rowSpace}(A)) = \text{rank}(A). \quad (221)$$

The converse does not hold, consider $P = A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$. □

Theorem 55. *Prove $\text{rank}(A + B) \leq \text{rank}(A) + \text{rank}(B)$.*

Proof. Let A, B have column stacked representations $(a_1 \cdots a_n), (b_1 \cdots b_n)$ respectively, and let $S_1 \subseteq \{a_i, i \in [n]\}$ be the basis for $\text{colSpace}(A)$ and $S_2 \subseteq \{b_i, i \in [n]\}$ be the basis for $\text{colSpace}(B)$. Then $\text{colSpace}(A + B) = \text{span}\{a_i + b_i | i \in [n]\} \subseteq \text{span}\{S_1 \cup S_2\}$, so $\text{rank}(A + B) = \dim(\text{colSpace}(A + B)) \leq \text{rank}(A) + \text{rank}(B)$. □

Exercise 48. *Let A be $m \times n$ matrix, then show that*

$$Ax = b \text{ consistent for all } b \in \mathbb{R}^m \implies A'y = 0 \text{ has only trivial solution.} \quad (222)$$

Proof. By rank nullity (Theorem 51), we have

$$\text{nullity}(A') = m - \text{rank}(A') = m - \text{rank}(A) = 0, \quad (223)$$

since $\text{rank}(A) = m$ by Theorem 47. □

Exercise 49. *Let A be $m \times n$ matrix.*

1. *Show that $\text{nullSpace}(A) = \text{nullSpace}(A'A)$.*
2. *Show that $\text{nullity}(A) = \text{nullity}(A'A)$ and that $\text{rank}(A) = \text{rank}(A'A)$.*

Determine if the following are true:

3. *$\text{nullity}(A) = \text{nullity}(AA')$.*
4. *$\text{rank}(A) = \text{rank}(AA')$.*

Proof. -

1. For $u \in \text{nullSpace}(A)$, see that $A'(Au) = 0$ and so $u \in \text{nullSpace}(A'A)$. Then $\text{nullSpace}(A) \subseteq$

$\text{nullSpace}(A'A)$. On the other hand, for $v \in \text{nullSpace}(A'A)$, and let $Av = \begin{pmatrix} b_1 \\ b_2 \\ \dots \\ b_m \end{pmatrix}$, then

$$(Av)'(Av) = v'A'Av = v'0 = 0 \implies \sum_i^m b_i^2 = 0 \implies \forall i \in [m], \quad b_i = 0. \quad (224)$$

Then $Av = 0, v \in \text{nullSpace}(A) \implies \text{nullSpace}(A'A) \subseteq \text{nullSpace}(A)$.

2. First part asserts that $\text{nullity}(A) = \text{nullity}(A'A)$. Rank nullity (Theorem 51) asserts that

$$\text{rank}(A) = n - \text{nullity}(A) = n - \text{nullity}(A'A) = \text{rank}(A'A). \quad (225)$$

3. False, by counterexample $A = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}$, where $AA' = \mathbb{1}_2$.
4. True, since $\text{rank}(A) = \text{rank}(A') = \text{rank}((A')'A') = \text{rank}(AA')$. We used Theorem 49.

□

Exercise 50. Determine which of these are true:

1. If $A \stackrel{\mathcal{R}}{\cong} B$, then $\text{rowSpace}(A') = \text{rowSpace}(B')$.
2. If $A \stackrel{\mathcal{R}}{\cong} B$, then $\text{colSpace}(A') = \text{colSpace}(B')$.
3. If $A \stackrel{\mathcal{R}}{\cong} B$, then $\text{nullSpace}(A') = \text{nullSpace}(B')$.
4. If A, B are matrices of same size, then $\text{rank}(A + B) = \text{rank}(A) + \text{rank}(B)$.
5. If A, B are matrices of same size, then $\text{nullity}(A + B) = \text{nullity}(A) + \text{nullity}(B)$.
6. If A is $n \times m$ matrix and B is $m \times n$ matrix, then $\text{rank}(AB) = \text{rank}(BA)$.
7. If A is $n \times m$ matrix and B is $m \times n$ matrix, then $\text{nullity}(AB) = \text{nullity}(BA)$.

Proof. -

1. False, by counterexample $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$.
2. True, since $\text{rowSpace}(A) = \text{rowSpace}(B)$ by invariance (Theorem 42) and $\text{rowSpace}(A) = \text{colSpace}(A')$.
3. False by counterexample $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$, $B = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$.
4. False by counterexample $A = B = \mathbb{1}_2$. See Theorem 55 for bound relation.
5. False by counterexample $A = B = 0_{2 \times 2}$.
6. False by counterexample $A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, $B = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$, where $AB = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$, $BA = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}$.
7. False by counterexample using the same matrices A, B defined in part 6.

□

3.1.5 Orthogonality

Definition 66 (\perp). For two objects a, b , $a \perp b$ means a is orthogonal to b .

Definition 67 (Vector p -norm, ℓ_p). Define the p -norm of a vector, for real $p \geq 1$ be called the ℓ_p norm of a vector, written

$$\|x\|_p := \left(\sum_{i=1}^n |x_i|^p \right)^{\frac{1}{p}}. \quad (226)$$

When written without the subscripts p , let $p = 2$, the euclidean norm (Definition 68). The vector norm is also said to be the length of a vector.

Definition 68 (Euclidean Norm). *The euclidean norm for x is the vector norm $\|x\|_2 = \sqrt{\sum x_i^2}$.*

Definition 69 (Vector Distance). *For two vectors $u, v \in \mathbb{R}^n$ defined, we say that their distance is $\|u-v\|_2$ and denote this $d(u, v)$.*

Consider a triangle with sides with length a, b, c respectively. Let the angle between the edges of side lengths a, b be θ . The cosine rule states that $c = \sqrt{a^2 + b^2 - 2ab \cos \theta}$. Now consider their vector analogues. $a \rightarrow u, b \rightarrow v, c \rightarrow (u - v)$ s.t.

$$\|u - v\|^2 = \|u\|^2 + \|v\|^2 - 2\|u\|\|v\| \cos \theta, \quad (227)$$

so

$$\theta = \arccos \left(\frac{\|u\|^2 + \|v\|^2 - \|u - v\|^2}{2\|u\|\|v\|} \right). \quad (228)$$

If the triangle was inscribed in a two dimensional surface with coordinates $u = (u_1, u_2), v = (v_1, v_2)$, then

$$d(u, v) = \sqrt{(u_1 - v_1)^2 + (u_2 - v_2)^2}, \quad (229)$$

and

$$\theta = \arccos \left(\frac{u_1^2 + u_2^2 + v_1^2 + v_2^2 - ((u_1 - v_1)^2 + (u_2 - v_2)^2)}{2\|u\|\|v\|} \right) \quad (230)$$

$$= \arccos \left(\frac{u_1 v_1 + u_2 v_2}{\|u\|\|v\|} \right) \quad (231)$$

Definition 70 (Dot/Inner Product). *For two vectors $u, v, \in \mathbb{R}^n$, the dot product of u, v is denoted*

$$u \cdot v := \sum_i^n u_i v_i. \quad (232)$$

Definition 71 (Unit Vectors). *A unit vector is vector v for which $\|v\| = 1$.*

Definition 72 (Angle). *The angle between two vectors $u, v \in \mathbb{R}^n$ is denoted*

$$\arccos \left(\frac{u \cdot v}{\|u\|\|v\|} \right). \quad (233)$$

We denote the angle between two vectors u, v to be $\angle(u, v)$.

From Definition 70, see that we may express the angle in the two dimensional problem (Equation 231) as $\arccos \left(\frac{u \cdot v}{\|u\|\|v\|} \right)$, which is consistent with the generalized statement in Definition 72.

Note that for column vectors u, v , the dot product $u \cdot v = u'v$.

Theorem 56 (Properties of the Dot Product). *For vectors $u, v, w \in \mathbb{R}^n, c \in \mathbb{R}$, the following hold:*

1. $u \cdot v = v \cdot u$.
2. $(u + v) \cdot w = u \cdot w + v \cdot w, w \cdot (u + v) = w \cdot u + w \cdot v$,
3. $(cu) \cdot v = u \cdot (cv) = c(u \cdot v)$,
4. $\|cu\| = |c|\|u\|$ and
5. $u \cdot u \geq 0$ and $u \cdot u = 0 \leftrightarrow u = 0$.

Proof. The proofs for these statements should follow directly from their Definitions. □

It is easy to see that $u \cdot u = \|u\|^2$ for arbitrary $u \in \mathbb{R}^n$.

3.1.5.1 Orthogonal Basis

Definition 73 (Orthogonality). *If two vectors $u, v \in \mathbb{R}^n$ satisfy $u \cdot v = 0$, we say the two vectors are orthogonal. Additionally, for a set $S \subseteq \mathbb{R}^n$, $\forall s_i, s_j, s_i \neq s_j \in S$, if $s_i \cdot s_j$ are orthogonal vectors, then we say that S is orthogonal set. In addition, if all the vectors in orthogonal set S is unit vector (Definition 71), then we say S is orthonormal set.*

Given two vectors $u, v \in \mathbb{R}^n$, if u is orthogonal to v , then their angle (Definition 72) is given by

$$\arccos(0) = \frac{\pi}{2}, \quad (234)$$

which in $\mathbb{R}^2, \mathbb{R}^3$ is the concept of perpendicularity.

Definition 74 (Normalization of Vectors and Sets). *For arbitrary vector v_i , see that $\tilde{v}_i = \frac{1}{\|v_i\|}v_i$ has norm one, since*

$$\|\tilde{v}_i\| = \left\| \frac{1}{\|v_i\|}v_i \right\| = \frac{1}{\|v_i\|}\|v_i\| = 1. \quad (235)$$

This is called normalizing a vector. See that for v_i, v_j that is orthogonal, normalization preserves orthogonality, since

$$\tilde{v}_i \cdot \tilde{v}_j = \left(\frac{1}{\|v_i\|}v_i \right) \cdot \left(\frac{1}{\|v_j\|}v_j \right) = \frac{1}{\|v_i\|\|v_j\|}(v_i \cdot v_j) = 0. \quad (236)$$

The process of converting an orthogonal set to orthonormal set by dividing each element by its norm is called normalizing a set.

See that standard basis e_i 's (Definition 56) is orthonormal.

Theorem 57 (Orthogonal Set S is LIND). *If S is orthogonal set (Definition 73) of nonzero vectors in vector space, then $LIND(S)$.*

Proof. Let $S = \{u_i, i \in [k]\}$. Consider HLS $\sum_i^k c_i u_i = 0$. Since S is orthogonal, we may write $(\sum_i^k c_i u_i) \cdot u_i = c_i(u_i \cdot u_i)$. Then since

$$\forall i \in [k], \quad c_i(u_i \cdot u_i) = \left(\sum c_i u_i \right) \cdot u_i = 0 \cdot u_i = 0 \quad (237)$$

but $u_i \neq 0$, c_i must be zero and the HLS must have only the trivial solution. S is linearly independent by Definition 52. \square

Corollary 5. *By equivalent statements for basis (Theorem 37) and linear independence of orthogonal sets, to see if some set S in vector space $\dim k$ is orthogonal basis, we only need to check orthogonality of S and $|S| = k$.*

Theorem 58. *If $S = \{u_i, i \in [k]\}$ be orthogonal basis for vector space V , then $\forall w \in V$, we may express*

$$w = \frac{w \cdot u_1}{u_1 \cdot u_1}u_1 + \cdots + \frac{w \cdot u_k}{u_k \cdot u_k}u_k. \quad (238)$$

That is $(w)_S = \left(\frac{w \cdot u_1}{u_1 \cdot u_1}, \dots, \frac{w \cdot u_k}{u_k \cdot u_k} \right)$. In particular, if S is orthonormal basis, then $(w)_S = (w \cdot u_1, \dots, w \cdot u_k)$.

Proof. Let $w = \sum_i^k c_i u_i$, then for $i \in [k]$, see that

$$w \cdot u_i = \left(\sum c_i \cdot u_i \right) \cdot u_i = c_i(u_i \cdot u_i), \quad (239)$$

and therefore $c_i = \frac{w \cdot u_i}{u_i \cdot u_i}$. The last assertion follows from observing $u_i \cdot u_i = \|u_i\|^2 = 1$ for all $i \in [k]$ under orthonormality. \square

Definition 75 (Orthogonality to Vector Space). Let V be subspace of \mathbb{R}^n , then we say that $u \in \mathbb{R}^n$ is orthogonal to V if $\forall v \in V$, u is orthogonal to v .

Definition 76 (Normal Vector). Let V be some subspace \mathbb{R}^n . If $\forall u \in V$, $\exists n$ s.t. $n \cdot u = 0$, then n is orthogonal to V (Definition 75) and we call n a normal vector of V .

For instance, if V is plane in \mathbb{R}^3 and V is s.t.

$$V = \{(x, y, z) \in \mathbb{R}^3 \mid ax + by + cz = 0\}, \quad (240)$$

where normal vector $n = (a, b, c)$, then $V = \{u \in \mathbb{R}^3 \mid n \cdot u = 0\}$.

Given a vector space V spanned by $S = \{u_i, i \in [k]\}$, to find all vectors orthogonal to V , we shall solve for the linear systems $v \cdot u_i = 0$, $i \in [k]$ for arbitrary vector $v \in V$. That is, solve for the HLS where

the vectors in S are row stacked, which is $\begin{pmatrix} u_1 \\ u_2 \\ \dots \\ u_k \end{pmatrix} V = \begin{pmatrix} u_1 V \\ u_2 V \\ \dots \\ u_k V \end{pmatrix} = 0$ (see Exercise 11). Formally:

Theorem 59. For $V = \text{span}\{u_i, i \in [k]\}$ subspace of \mathbb{R}^n , vector $v \in \mathbb{R}^n$ is orthogonal to V iff $v \cdot u_i = 0$ for all $i \in [k]$.

Definition 77 (Orthogonal Projection). Let V be subspace \mathbb{R}^n , then every vector $u \in \mathbb{R}^n$ may be written uniquely as form

$$u = p + n, \quad (241)$$

where n is orthogonal to V and $p \in V$. We call p the projection of u onto V .

Theorem 60 (Projections with Basis). Let V be subspace of \mathbb{R}^n , w be vector in \mathbb{R}^n , then if $S = \{u_i, i \in [k]\}$ is orthogonal basis for V , we have

$$p := \sum_i^k \frac{w \cdot u_i}{u_i \cdot u_i} u_i, \quad (242)$$

where p is projection of w onto V (Definition 77). Additionally, if S is orthonormal basis, then

$$p = \sum_i^k (w \cdot u_i) u_i. \quad (243)$$

Proof. Define $p := \sum_i^k \frac{w \cdot u_i}{u_i \cdot u_i} u_i$ and $n := w - p$, then $\forall i \in [k]$, see that

$$n \cdot u_i = w \cdot u_i - p \cdot u_i \quad (244)$$

$$= w \cdot u_i - \sum_j^k \frac{w \cdot u_j}{u_j \cdot u_j} (u_j \cdot u_i) \quad (245)$$

$$= w \cdot u_i - \frac{w \cdot u_i}{u_i \cdot u_i} (u_i \cdot u_i) \quad (246)$$

$$= 0. \quad (247)$$

The last assertion follows from $u_i \cdot u_i = 1$ for all $i \in [k]$ under orthonormality. \square

See that Theorem 58 is consistent with Theorem 60 by $w \rightarrow p, n \rightarrow 0$.

Theorem 61 (Gram-Schmidt Process). Let $S = \{u_i, i \in [k]\}$ be basis for vector space V , let

$$\forall i \in [k], \quad v_i := u_i - \sum_{j=1}^{i-1} \frac{u_i \cdot v_j}{v_j \cdot v_j} v_j. \quad (248)$$

Then $\{v_i, i \in [k]\}$ is orthogonal basis for V . Divide each element v_i by $\|v_i\|$ in orthogonal basis to get orthonormal basis (see Definition 74).

Proof. First, see from the algorithm that each of the v_i 's are linear combinations of the u_i 's, which span V with dimension k . By span closure, each of the v_i 's $\in V$. Additionally, there a total of k such v_i 's, so by Corollary 5, we only need to show orthogonality of the v_i 's. When we have $\{v_1\}$, this set is vacuously an orthogonal set. Suppose sets of size l , $S = \{v_t, t \in [l]\}$, $l < i$ are orthogonal. Then consider for $l < i$,

$$v_i \cdot v_l = \left(u_i - \sum_{j=1}^{i-1} \frac{u_i \cdot v_j}{v_j \cdot v_j} v_j \right) \cdot v_l \quad (249)$$

$$= u_i \cdot v_l - \frac{v_i \cdot v_l}{v_l \cdot v_l} v_l \cdot v_l \quad (250)$$

$$= 0. \quad (251)$$

So v_i is orthogonal to elements of the set v_{i-1} , which by inductive assumption is orthogonal. That is the addition of v_i keeps orthogonality invariant. Then by induction $\{v_i, i \in [k]\}$ are orthogonal and we are done. \square

Exercise 51 (Gram-Schmidt Process Run). Apply Gram-Schmidt (Theorem 61) to transform $\{u_1, u_2, u_3\}$ for \mathbb{R}^3 into orthogonal basis, where $u_1 = (1, -1, 2), u_2 = (2, 1, 0), u_3 = (0, 0, 1)$.

Proof. Work through these iteratively:

$$v_1 = u_1, \quad (252)$$

$$v_2 = u_2 - \frac{u_2 \cdot v_1}{v_1 \cdot v_1} v_1, \quad (253)$$

$$v_3 = u_3 - \frac{u_3 \cdot v_1}{v_1 \cdot v_1} v_1 - \frac{u_3 \cdot v_2}{v_2 \cdot v_2} v_2 \quad (254)$$

to obtain the orthogonal vectors. \square

3.1.5.2 Best Approximations

Theorem 62 (Best Approximation Theorem). Let V be subspace of \mathbb{R}^n . If $u \in \mathbb{R}^n$ and p is projection of u onto V (Definition 77), then

$$\forall v \in V, \quad d(u, p) \leq d(u, v). \quad (255)$$

That is p is the best approximation for vector u that is in vector space V .

Proof. For arbitrary $v \in V$, let

$$n := u - p, \quad w := p - v, \quad x := u - v. \quad (256)$$

Then see $x = n + w$ and $n \cdot w = 0$. So

$$\|x\|^2 = x \cdot x = (n + w) \cdot (n + w) = n \cdot n + w \cdot w = \|n\|^2 + \|w\|^2. \quad (257)$$

Therefore $\|x\|^2 \geq \|n\|^2$ and

$$d(u, p) = \|u - p\| = \|n\| \leq \|x\| = \|u - v\| = d(u, v). \quad (258)$$

□

To find the shortest distance of some vector u to a vector space V , find the projection p of u onto V and compute $d(u, p)$.

Exercise 52 (Least-Squares Method). *Suppose the random variables for r, s, t are related*

$$t = cr + ds + e, \quad (259)$$

for constants c, d, e . Suppose we have observations for $(r, s, t)_i, i \in [6]$, and we would like to estimate the (beta) coefficients for c, d, e so we have a better understanding the relationships between the random

variables. Defining $A = \begin{pmatrix} r_1 & s_1 & 1 \\ r_2 & s_2 & 1 \\ \dots & \dots & \dots \\ r_6 & s_6 & 1 \end{pmatrix}, x = \begin{pmatrix} c \\ d \\ e \end{pmatrix}, b = \begin{pmatrix} t_1 \\ t_2 \\ \dots \\ t_6 \end{pmatrix}$, we would like to solve for

$Ax = b$. However, it turns out that due to the presence of random errors, $Ax = b$ is almost always inconsistent. Instead, we would like to find the best fit estimates $(\hat{c}, \hat{d}, \hat{e})$ for (c, d, e) . The least squares method minimizes the sum of squared errors proposed by the model; it solves for the x that minimizes $\|b - Ax\|^2$. This statement is equivalent to the form in Equation 1025 in our discussion on multiple least-squares method. For $m \times n$ matrix A , the least-squares solution is the vector $u \in \mathbb{R}^n$ that satisfies

$$\forall v \in \mathbb{R}^n, \quad \|b - Au\| \leq \|b - Av\|. \quad (260)$$

See Theorem 46 that we may express $\text{colSpace}(A) = \{Av | v \in \mathbb{R}^n\}$. It turns out that the least squares solution b is the best approximation of b onto $\text{colSpace}(A)$.

Theorem 63. *Let $Ax = b$ be linear system for $m \times n$ matrix, and p be projection of b onto $\text{colSpace}(A)$. Then*

$$\forall v \in \mathbb{R}^n, \quad \|b - p\| \leq \|b - Av\|. \quad (261)$$

That is u is least-square solution to $Ax = b$ iff $Au = p$.

Proof. By Best Approximation Theorem 62, see that

$$\forall w \in \text{colSpace}(A), \quad \|b - p\| = d(b, p) \leq d(b, w) = \|b - w\|, \quad (262)$$

and since $\text{colSpace}(A) = \{Av | v \in \mathbb{R}^n\}$, the result follows. □

In Equation 1030, we obtained the least-squares solution via matrix calculus. Here we derive the same solution using the linear algebraic theorems.

Theorem 64 (Obtaining the Least Squares Solution). *Let $Ax = b$ be linear system. Then u is least squares solution iff u solves $A'Ax = A'b$.*

Proof. Let $A = \begin{pmatrix} a_1 & a_2 & \dots & a_n \end{pmatrix}$ where a_i is column i . Let $V = \text{colSpace}(A)$, then u is least squares solution to $Ax = b$ iff Au is projection of b onto V iff $(b - Au)$ is orthogonal to V iff $(b - Au)$ is orthogonal to vectors in the span of V , that is $\{a_i, i \in [n]\}$. This is linear system

$$\forall i \in [n], \quad a_i \cdot (b - Au) = 0 \quad (263)$$

which is $A'(b - Au) = 0$ by block matrix representations and therefore $A'Au = A'b$. We used the best approximation Theorem 62, definitions for vector space orthogonality (Definition 75), column space representations (Theorem 46) and block matrix operations (Exercise 11). \square

That is, we do not need to explicitly solve for projection p - we may instead solve for the linear system $(A'A)x = A'b$. In the form for Equation 1030, we have assumed that the matrix A is full rank, st. $A'A$ is invertible (verify this) and a unique least squares solution exists. Here, we have shown a more generalized problem without assuming a unique least squares solution. If the linear system $A'Ax = A'b$ has infinitely many solutions, pick some vector u from the solution space and compute $Au := p$ as the projection of b onto V .

3.1.5.3 Orthogonal Matrices

Recall that for $S = \{u_i, i \in [k]\}, T = \{v_i, i \in [k]\}$ bases for vector space V , the transition matrix P from $S \rightarrow T$ (Definition 59) is written

$$P = \begin{pmatrix} [u_1]_T & [u_2]_T & \cdots & [u_k]_T \end{pmatrix} \quad (264)$$

and $[w]_T = P[w]_S$ is satisfied for $w \in V$.

Definition 78 (Orthogonal Matrix). *A square matrix (Definition 22) is orthogonal if $A^{-1} = A'$.*

Theorem 65. *A square matrix A is orthogonal iff $AA' = \mathbb{1}$.*

Proof. Proof follows directly from Theorem 13. \square

Theorem 66 (Equivalent Statements for Matrix Orthogonality). *Let A be square matrix order n , then the following statements are equivalent:*

1. *A is orthogonal,*
2. *Rows of A form orthonormal basis for \mathbb{R}^n .*
3. *Columns of A form orthonormal basis for \mathbb{R}^n .*

Proof. Let $A = \begin{pmatrix} a_1 \\ a_2 \\ \cdots \\ a_n \end{pmatrix}$ be the row-stacked representation of A . the By Corollary 5, $1 \leftrightarrow 2$ can be proved

if we show that A orthogonal iff $\{a_i, i \in [n]\}$ is orthonormal. See that

$$AA' = (a_i a'_j)_{n \times n} = (a_i \cdot a_j)_{n \times n}, \quad (265)$$

so A orthogonal iff $AA' = \mathbb{1}$ iff $\forall i, j, a_i \cdot a_j = \delta_{ij}$ is the Dirac delta function $\delta_{ij} = \mathbb{1}\{i = j\}$. The last statement iff a_1, \cdots, a_n is orthonormal. Proof for $1 \leftrightarrow 3$ is similar. \square

Theorem 67. *Let S, T be two orthonormal bases for vector space, P be transition matrix $S \rightarrow T$. Then, P is orthogonal and $PP' = \mathbb{1}$. P' is transition matrix from $T \rightarrow S$.*

Proof. Let $S = \{u_i, i \in [k]\}, T = \{v_i, i \in [k]\}$ be two orthonormal bases given. Then by orthonormality we may express (Theorem 58)

$$\forall i \in [k], \quad u_i = \sum_i^k (u_i \cdot v_i) v_i. \quad (266)$$

Then transition matrix P from $S \rightarrow T$ is expressed

$$\begin{pmatrix} u_1 \cdot v_1 & u_2 \cdot v_1 & \cdots & u_k \cdot v_1 \\ u_1 \cdot v_2 & u_2 \cdot v_2 & \cdots & u_k \cdot v_2 \\ \cdots & \cdots & \cdots & \cdots \\ u_1 \cdot v_k & u_2 \cdot v_k & \cdots & u_k \cdot v_k \end{pmatrix}. \quad (267)$$

We may repeat the same exercise and verify that the transition matrix Q from $T \rightarrow S$ is s.t. $Q' = P$. The final assertion follows from Theorem 40. \square

Exercise 53 (Rotation of Coordinates). *Let $E = \{e_1, e_2\}$ be standard basis (Definition 56) for \mathbb{R}^2 . We may obtain a rotation in the coordinate system by angle θ . See that if we let*

$$(u_1)_E = (\cos(\theta), \sin(\theta)), \quad (268)$$

$$(u_2)_E = (-\sin(\theta), \cos(\theta)), \quad (269)$$

then $S = \{u_1, u_2\}$ is orthonormal basis for \mathbb{R}^2 and the transition matrix from $S \rightarrow E$ is

$$P = \begin{pmatrix} \cos(\theta) & -\sin(\theta) \\ \sin(\theta) & \cos(\theta) \end{pmatrix}. \quad (270)$$

For arbitrary $v = (x, y) \in \mathbb{R}^2$, $(v)_S = (x', y')$ is obtained via the relation

$$\begin{pmatrix} x' \\ y' \end{pmatrix} = P' \begin{pmatrix} x \\ y \end{pmatrix} \quad (271)$$

s.t.

$$x' = x \cos(\theta) + y \sin(\theta) \quad (272)$$

$$y' = -x \sin(\theta) + y \cos(\theta), \quad (273)$$

which is the rotation by θ to a new coordinate system.

Theorem 68 (Cauchy-Schwarz Inequality). *For vectors $u, v \in \mathbb{R}^n$, prove*

$$|u \cdot v| \leq \|u\| \|v\|. \quad (274)$$

Proof. If $u = 0$, then $|0 \cdot v| \leq \|0\| \|v\|$. Else, if $u \neq 0$, then denote

$$a = u \cdot u, \quad b = 2u \cdot v, \quad c = v \cdot v, \quad (275)$$

and $\forall t \in \mathbb{R}$, see that

$$0 \leq (tu + v)(tu + v) = t^2(u \cdot u) + 2tu \cdot v + v \cdot v = at^2 + bt + c. \quad (276)$$

Since this is strictly greater than zero, the discriminant $b^2 - 4ac \leq 0$, so

$$4(u \cdot v)^2 \leq 4(u \cdot u)(v \cdot v) \implies (u \cdot v)^2 \leq (u \cdot u)(v \cdot v) \implies |(u \cdot v)| \leq \sqrt{u \cdot u} \sqrt{v \cdot v} = \|u\| \|v\|. \quad (277)$$

\square

Theorem 69 (Triangle Inequality). *For vectors $u, v \in \mathbb{R}^n$, prove*

$$\|u + v\| \leq \|u\| + \|v\|. \quad (278)$$

Proof. We can write

$$\|u + v\|^2 = (u + v) \cdot (u + v) \quad (279)$$

$$= u \cdot u + v \cdot v + 2u \cdot v \quad (280)$$

$$\leq \|u\|^2 + \|v\|^2 + 2\|u\|\|v\| \quad \text{Theorem 68} \quad (281)$$

$$= (\|u\| + \|v\|)^2. \quad (282)$$

The result follows. \square

Exercise 54. Prove that for $u, v, w \in \mathbb{R}^n$,

1.

$$d(u, w) \leq d(u, v) + d(v, w). \quad (283)$$

2.

$$\|u + v\|^2 + \|u - v\|^2 = 2\|u\|^2 + 2\|v\|^2. \quad (284)$$

3.

$$u \cdot v = \frac{1}{4}\|u + v\|^2 - \frac{1}{4}\|u - v\|^2. \quad (285)$$

Proof. -

1. Use the Triangle Inequality (Theorem 69 with $u \rightarrow u - v$, $v \rightarrow v - w$ and so

$$\|u - w\| \leq \|u - v\| + \|v - w\| \leftrightarrow d(u, w) \leq d(u, v) + d(v, w). \quad (286)$$

2. See that

$$\|u + v\|^2 + \|u - v\|^2 = (u + v) \cdot (u + v) + (u - v) \cdot (u - v) \quad (287)$$

$$= 2(u \cdot u) + 2(v \cdot v) + 2u \cdot v - 2u \cdot v \quad (288)$$

$$= 2\|u\|^2 + 2\|v\|^2. \quad (289)$$

This part shows that for a parallelogram with u, v as sides, then taking the sum of squares of the four sides is the sum of squares of the diagonals.

3. See that

$$\frac{1}{4}(u + v) \cdot (u + v) - \frac{1}{4}(u - v) \cdot (u - v) = \frac{1}{4}(2u \cdot v + 2u \cdot v) = u \cdot v. \quad (290)$$

\square

Exercise 55 (Orthogonal Space is Subspace). Let W be subspace of \mathbb{R}^n , and define

$$W^\perp = \{u \in \mathbb{R}^n \mid u \text{ orthogonal to } W \}. \quad (291)$$

Show W^\perp is subspace of \mathbb{R}^n .

Proof. Let $\{w_i, i \in [k]\}$ be a basis for W , then see that

$$u \in W^\perp \leftrightarrow \forall i \in [k], w_i \cdot u = 0 \leftrightarrow \begin{pmatrix} w_1 \\ \dots \\ w_k \end{pmatrix} u = 0. \quad (292)$$

Therefore W^\perp is a nullspace. □

Exercise 56. Let $\{u_1, \dots, u_n\}$ be set of orthogonal vectors, then show

$$\left\| \sum_i^n u_i \right\|^2 = \sum_i^n \|u_i\|^2. \quad (293)$$

Proof. Write

$$\left\| \sum_i^n u_i \right\|^2 = \left(\sum_i^n u_i \right) \cdot \left(\sum_j^n u_j \right) = \sum_i^n (u_i \cdot u_i) = \sum_i^n \|u_i\|^2. \quad (294)$$

□

Exercise 57 (QR Factorization Example). Let $A = \begin{pmatrix} 1 & 1 & 0 \\ 1 & 1 & 0 \\ 1 & 1 & 1 \\ 0 & 1 & 1 \end{pmatrix}$ and

$$u_1 = \begin{pmatrix} 1 \\ 1 \\ 1 \\ 0 \end{pmatrix}, \quad u_2 = \begin{pmatrix} 1 \\ 1 \\ 1 \\ 1 \end{pmatrix}, \quad u_3 = \begin{pmatrix} 0 \\ 0 \\ 1 \\ 1 \end{pmatrix}. \quad (295)$$

Use Gram-Schmidt process to transform $\{u_1, u_2, u_3\}$ into orthonormal basis $\{w_1, w_2, w_3\}$ for $\text{colSpace}(A)$. Then write each of the u_i 's as linear combination of w_i 's. Then write $A = QR$, where Q is 4×3 matrix where the columns are orthonormal, and R is 3×3 upper triangular with positive entries along the diagonal.

Proof. Apply Gram-Schmidt (Theorem 61) to obtain orthonormal basis

$$w_1 = \frac{1}{\sqrt{3}} \begin{pmatrix} 1 \\ 1 \\ 1 \\ 0 \end{pmatrix}, \quad w_2 = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \end{pmatrix}, \quad w_3 = \frac{1}{\sqrt{6}} \begin{pmatrix} -1 \\ -1 \\ 2 \\ 0 \end{pmatrix}. \quad (296)$$

See that

$$u_1 = \sqrt{3}w_1, \quad u_2 = \sqrt{3}w_1 + w_2, \quad u_3 = \frac{1}{\sqrt{3}}w_1 + w_2 + \sqrt{\frac{2}{3}}w_3. \quad (297)$$

Then let the matrices

$$A = (u_1 \ u_2 \ u_3) = (w_1 \ w_2 \ w_3) \begin{pmatrix} \sqrt{3} & \sqrt{3} & \frac{1}{\sqrt{3}} \\ 0 & 1 & 1 \\ 0 & 0 & \sqrt{\frac{2}{3}} \end{pmatrix}, \quad (298)$$

$$Q = (w_1 \ w_2 \ w_3) = \begin{pmatrix} \frac{1}{\sqrt{3}} & 0 & -\frac{1}{\sqrt{6}} \\ \frac{1}{\sqrt{3}} & 0 & -\frac{1}{\sqrt{6}} \\ \frac{1}{\sqrt{3}} & 0 & \frac{2}{\sqrt{6}} \\ 0 & 1 & 0 \end{pmatrix}, \quad R = \begin{pmatrix} \sqrt{3} & \sqrt{3} & \frac{1}{\sqrt{3}} \\ 0 & 1 & 1 \\ 0 & 0 & \sqrt{\frac{2}{3}} \end{pmatrix} \quad (299)$$

satisfy $A = QR$. □

Theorem 70 (Unique Projection). *Let V be subspace of \mathbb{R}^n , and $u \in \mathbb{R}^n$. Show that $u = n + p$, where n is orthogonal to V and p is projection of u onto V is unique.*

Proof. Let $u = n_1 + p_1 = n_2 + p_2$. We show that the two representations must be the same. Since for $i = 1, 2$ we have $n_i \cdot p_j = 0$, and $n_1 + p_1 = n_2 + p_2 \implies n_1 - n_2 = p_2 - p_1$, then

$$\|n_1 - n_2\|^2 = (n_1 - n_2) \cdot (n_1 - n_2) = (n_1 - n_2) \cdot (p_2 - p_1) = n_1 \cdot p_2 - n_1 \cdot p_1 - n_2 \cdot p_2 + n_2 \cdot p_1 = 0. \quad (300)$$

Therefore, $n_1 - n_2 = 0$ and so $n_1 = n_2$. We also have $p_2 - p_1 = n_1 - n_2 = 0$, so $p_1 = p_2$. □

Exercise 58. *Let A be square matrix order n , and $A^2 = A$, $A' = A$. Then*

1. Show that $\forall u, v \in \mathbb{R}^n$, $(Au) \cdot v = u \cdot (Av)$.
2. Show that $\forall w \in \mathbb{R}^n$, Aw is projection of w onto subspace $V = \{u \in \mathbb{R}^n | Au = u\}$ of \mathbb{R}^n .

Proof. -

1. $(Au) \cdot v = (Au)'v = u'Av = u \cdot (Av)$.
2. Since $A(Aw) = A^2w = Aw \in V$, then for $v := w - Aw$, see that for all $u \in V$ (applying part 1 and using the property $Au = u$ of elements in subspace V),

$$u \cdot v = u \cdot w - u \cdot Aw = u \cdot w - Au \cdot w = u \cdot w - u \cdot w = 0. \quad (301)$$

Since $w = Aw + v$, $Aw \in V$ and $v \perp V$, Aw is projection w onto V . □

Exercise 59. *Discuss which of these are true:*

1. $\|u\| = \|v\| \implies \|u + w\| = \|v + w\|$.
2. $\|u\| = \|v\|$ and w orthogonal to $u, v \implies \|u + w\| = \|v + w\|$.
3. u orthogonal to $v, w \implies u$ orthogonal to $v + w$.
4. u, v orthogonal and v, w orthogonal $\implies u, w$ orthogonal.

Proof. -

1. False, see counterexample $u, v, w = (1, 0), (0, 1), (2, 0)$ respectively.
2. True, since $\|u + w\| = \sqrt{\|u\|^2 + \|w\|^2}$, $\|v + w\| = \sqrt{\|v\|^2 + \|w\|^2}$.
3. True, $u \cdot (v + w) = u \cdot v + u \cdot w = 0$.
4. False, see counterexample $u, v, w = (1, 0), (0, 1), (2, 0)$ respectively. □

Exercise 60. *Suppose a linear system $Ax = b$ is consistent, then show that the solution space of $Ax = b$ is the solution space of $A'Ax = A'b$.*

Proof. If $Av = b$, then since $A'Av = A'Av = A'b$, v is solution for $A'Ax = A'b$. Then the solution for space for $Ax = b$ is written (Theorem 52, Exercise 49 part 1)

$$\{u + v | u \in \text{nullSpace}(A)\} = \{u + v | u \in \text{nullSpace}(A'A)\}, \quad (302)$$

which is the solution space for $A'Ax = A'b$. □

Exercise 61. Let A be orthogonal matrix order n and $u, v \in \mathbb{R}^n$. Show that

1. $\|u\| = \|Au\|$.
2. $d(u, v) = d(Au, Av)$.
3. $\angle(u, v) = \angle(Au, Av)$.

Proof. -

1. $\|Au\|^2 = (Au)'(Au) = u'A'Au = u'u = \|u\|^2$.
2. $d(Au, Av) = \|Au - Av\| = \|A(u - v)\| = \|u - v\| = d(u, v)$ by part 1.
3. $(Au) \cdot (Av) = u'A'Av = u'v = u \cdot v \implies \angle(u, v) = \arccos\left(\frac{u \cdot v}{\|u\|\|v\|}\right) = \arccos\left(\frac{(Au) \cdot (Av)}{\|Au\|\|Av\|}\right) = \angle(Au, Av)$ by part 1.

□

Exercise 62. Let A be orthogonal matrix order n and $S = \{u_i, i \in [n]\}$ be basis for \mathbb{R}^n .

1. Show that $T = \{Au_i, i \in [n]\}$ is basis for \mathbb{R}^n .
2. Show that S orthogonal $\implies T$ orthogonal.
3. Show that S orthonormal $\implies T$ orthonormal. (Orthogonal (unitary) matrices preserve vector norms).

Proof. -

1. Since $A^{-1} = A'$ then T is linearly independent by Exercise 39. So T is basis by Theorem 37.
2. Follows immediately from Exercise 61, since $(Au) \cdot (Av) = u \cdot v$.
3. Part 3 asserts that T is minimally orthogonal set. Then to show orthonormality, see Exercise 61, part 1. That is, vector norms are preserved under transformations from orthogonal (more generally, unitary) matrices.

□

Exercise 63. Determine which of these are true:

1. If $A = (c_1 \cdots c_k)$ is $n \times k$ matrix and $c_i, i \in [k]$ orthonormal then $A'A = \mathbb{1}_k$.
2. If $A = (c_1 \cdots c_k)$ is $n \times k$ matrix and $c_i, i \in [k]$ orthonormal then $AA' = \mathbb{1}_n$.
3. If A, B orthogonal matrices, then $A + B$ is orthogonal.
4. If A, B orthogonal matrices, then AB is orthogonal.

Proof. -

1. True, since $A'A = \begin{pmatrix} c'_1 \\ \dots \\ c'_k \end{pmatrix} \begin{pmatrix} c_1 & \dots & c_k \end{pmatrix} = (c_i \cdot c_j)_{k \times k} = \mathbb{1}_k$.
2. False by counterexample $A = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{pmatrix}$. Also, recall that A has right inverse iff $\text{rank}(A) = n$ but here $\text{rank}(A) = 2 < 3$ (Theorem 53).
3. False by counterexample $A = \mathbb{1}_2, B = -\mathbb{1}_2$.
4. True, since $(AB)'(AB) = B'A'AB = \mathbb{1}$.

□

3.1.6 Diagonalization

All vectors here are expressed column unless otherwise stated.

3.1.6.1 Eigenvalues

Definition 79 (Eigenvalues and Eigenvectors). *Let A be square matrix order n , then nonzero $u \in \mathbb{R}^n$ is eigenvector of A if $Au = \lambda u$ for some constant λ . λ is said to be eigenvalue of A , and u is said to be eigenvector of A associated with eigenvalue λ .*

Definition 80 (Characteristic Polynomials). *Let A be square matrix order n . Then the equation*

$$\det(\lambda \mathbb{1} - A) = 0 \tag{303}$$

is said to be a characteristic equation of A with characteristic polynomial $\det(\lambda \mathbb{1} - A)$.

Theorem 71 (Eigenvalue solves the characteristic polynomial). *Let A be square matrix order n , then λ is eigenvalue of A iff $\det(\lambda \mathbb{1} - A) = 0$.*

Proof. λ is eigenvalue of A iff $Au = \lambda u$ for some nonzero $u \in \mathbb{R}^n$ iff $\lambda u - Au = 0$ iff $(\lambda \mathbb{1} - A)u = 0$ iff $(\lambda \mathbb{1} - A)x = 0$ has non-trivial solutions iff $\det(\lambda \mathbb{1} - A) = 0$, by Theorem 39. When expanded $\det(\lambda \mathbb{1} - A) = 0$ turns out to be polynomial in λ of degree n . (verify this) □

Exercise 64. *For matrix $C = \begin{pmatrix} 0 & -1 & 0 \\ 0 & 0 & 2 \\ 1 & 1 & 1 \end{pmatrix}$, the characteristic polynomial is*

$$\det(\lambda \mathbb{1} - C) = \begin{vmatrix} \lambda & 1 & 0 \\ 0 & \lambda & -2 \\ -1 & -1 & \lambda - 1 \end{vmatrix} = \lambda^3 - \lambda^2 - 2\lambda + 2 = (\lambda - 1)(\lambda^2 - 2), \tag{304}$$

so $\det(\lambda \mathbb{1} - C) = 0$ iff $\lambda \in \{1, \sqrt{2}, -\sqrt{2}\}$ which are the eigenvalues of C .

Theorem 72 (Invertibility of Square Matrices, 3). *If A is square matrix order n , then the following statements are equivalent:*

1. A is invertible.
2. $Ax = 0$ has only the trivial solution.
3. RREF of A is identity $\mathbb{1}$ matrix.
4. A can be expressed as $\Pi_i^n E_i$, where E_i are elementary matrices.
5. $\det(A) \neq 0$.
6. Rows of A form basis for \mathbb{R}^n .
7. Columns of A form basis for \mathbb{R}^n .
8. $\text{rank}(A) = n$.
9. 0 is not eigenvalue of A .

Proof. See proof in Theorem 39 for the iff conditions for statement $1 \leftrightarrow 7$. Statement $6, 7 \leftrightarrow 8$ is trivial by definition of rank (Definition 62). We just need to show any of statements $1 \sim 8$ iff statement 9. By Theorem 71, λ is eigenvalue of A iff $\det(\lambda\mathbb{1} - A) = 0$, so 0 is not eigenvalue of A iff $\det(0 - A) = \det(-A) = (-1)^n \det(A) \neq 0$ (last step follows from Theorem 22), which is iff $\det(A) \neq 0$. Then we are done. \square

Theorem 73. *If A is triangular matrix (Definition 28), then the eigenvalues of A are diagonal entries of A .*

Proof. Suppose $A = (a_{ij})$ order n is triangular, then consider $\lambda\mathbb{1} - A$. This is triangular matrix with diagonals $\lambda - a_{ii}$, $i \in [n]$, so by Theorem 16, see that

$$\det(\lambda\mathbb{1} - A) = \prod_i^n (\lambda - a_{ii}). \quad (305)$$

It follows that the diagonal entries a_{ii} are the eigenvalues of A . \square

Definition 81 (Eigenspace). *Let A be square matrix order n and λ be eigenvalue, then solution space of $(\lambda\mathbb{1} - A)x = 0$ is called the eigenspace of A associated with eigenvalue λ , and we denote this E_λ . See that this is a nullspace. If nonzero $u \in E_\lambda$, then u must be an eigenvector of A associated with λ ; $Au = \lambda u$.*

We know how to obtain the eigenvalues of a matrix A . See Exercise 64 on solving characteristic polynomials. Once we obtain some set of eigenvalues, then each eigenvalue has an associated eigenspace, which can be obtained by solving some HLS. We know how to obtain the spanning basis (Definition 54) for nullspaces (Definition 64). See Exercise 33 for a walk-through.

3.1.6.2 Diagonalization

Definition 82 (Diagonalizable Matrix). *Let A be square matrix order n , then we say that it is diagonalizable if $\exists P$ that is invertible s.t. $P^{-1}AP = D$ and D is diagonal matrix. Then P is said to diagonalize matrix A .*

Theorem 74. *Let A is square matrix order n , then A is diagonalizable iff A has n linearly independent eigenvectors.*

Proof. \rightarrow : Suppose A is diagonalizable, then let P be invertible matrix satisfying $P^{-1}AP = D$ where

$$D_{ii} = \begin{cases} \lambda_i & \text{if } i = j, \\ 0 & \text{if } i \neq j. \end{cases} \quad (306)$$

For $P = (u_1 \ u_2 \ \cdots \ u_n)$, since $AP = PD$, then

$$A(u_1 \ u_2 \ \cdots \ u_n) = (u_1 \ u_2 \ \cdots \ u_n)D \implies (Au_1 \ Au_2 \ \cdots \ Au_n) = (\lambda_1 u_1 \ \lambda_2 u_2 \ \cdots \ \lambda_n u_n) \quad (307)$$

so that $Au_i = \lambda_i u_i$ for all i . That is, u_1, \dots, u_n are eigenvectors of A , and since P is invertible, by equivalent statements (Theorem 72), it follows that $\{u_i, i \in [n]\}$ is \mathbb{R}^n basis; they are linearly independent.

\leftarrow : Suppose A has n linearly independent eigenvectors $u_i, i \in [n]$. Let these be associated with the eigenvalues $\lambda_i, i \in [n]$, then by equivalent statements for basis (Theorem 37), it follows that $\{u_i, i \in [n]\}$ is basis for \mathbb{R}^n . Then define $P = (u_1 \ u_2 \ \cdots \ u_n)$, and see that

$$AP = (Au_1 \ Au_2 \ \cdots \ Au_n) = (\lambda_1 u_1 \ \lambda_2 u_2 \ \cdots \ \lambda_n u_n) = PD, \quad (308)$$

where

$$D_{ii} = \begin{cases} \lambda_i & \text{if } i = j, \\ 0 & \text{if } i \neq j. \end{cases} \quad (309)$$

By the equivalence relations asserted by Theorem 72, P is invertible and $P^{-1}AP = D$. \square

Exercise 65. Given a square matrix A order n , discuss how one may determine if A is diagonalizable, and if it is so, outline how to find invertible P s.t. $P^{-1}AP = D$ for some diagonal matrix D .

Proof. 1. First, find all distinct eigenvalues $\lambda_i, i \in [k]$ by solving for the characteristic equation $\det(\lambda \mathbb{1} - A) = 0$.

2. For each $i \in [k]$, find basis S_{λ_i} for eigenspace E_{λ_i} by solving the associated HLS.

3. Let $S = \cup_i^k S_{\lambda_i}$, if $|S| < n$, then A is not diagonalizable, and otherwise it is diagonalizable. Suppose $S = \{u_1, \dots, u_n\}$, then the matrix $P = (u_1 \ u_2 \ \cdots \ u_n)$ is invertible matrix diagonalizing A .

The case when matrix A has non-real eigenvalues when solving for the characteristic polynomial are discussed in the section on abstract linear algebra techniques over complex fields. \square

Result 4. Suppose the characteristic polynomial of matrix A is factorized to $\det(\lambda \mathbb{1} - A) = \prod_i^k (\lambda - \lambda_i)^{r_i}$, then for each eigenvalue λ_i , $\dim(E_{\lambda_i}) \leq r_i$. Furthermore, A is diagonalizable iff in step 2 outlined in algorithm for Exercise 65, we obtain $\forall i \in [k], \dim(E_{\lambda_i}) = r_i$.

Exercise 66. -

1. Let $C = \begin{pmatrix} 0 & -1 & 0 \\ 0 & 0 & 2 \\ 1 & 1 & 1 \end{pmatrix}$. Solving the characteristic polynomial (see Exercise 64), the eigenvalues

are $1, \sqrt{2}, -\sqrt{2}$. Solving the linear system for $\lambda = 1$, $(\lambda \mathbb{1} - C)x = 0$,

$$\begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & -2 \\ -1 & -1 & 1-1 \end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}, \quad (310)$$

get general solution $\begin{pmatrix} x \\ y \\ z \end{pmatrix} = t \begin{pmatrix} -2 \\ 2 \\ 1 \end{pmatrix}$. Then $E_1 = \text{span} \left\{ \begin{pmatrix} -2 \\ 2 \\ 1 \end{pmatrix} \right\}$. We may repeat the same exercise to get

$$E_{\sqrt{2}} = \text{span} \left\{ \begin{pmatrix} -1 \\ \sqrt{2} \\ 1 \end{pmatrix} \right\}, \quad E_{-\sqrt{2}} = \text{span} \left\{ \begin{pmatrix} -1 \\ -\sqrt{2} \\ 1 \end{pmatrix} \right\}. \quad (311)$$

Then let $P = \begin{pmatrix} -2 & -1 & -1 \\ 2 & \sqrt{2} & -\sqrt{2} \\ 1 & 1 & 1 \end{pmatrix}$ and $P^{-1}CP = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \sqrt{2} & 0 \\ 0 & 0 & -\sqrt{2} \end{pmatrix}$.

2. Let $A = \begin{pmatrix} 1 & 0 & 0 \\ 1 & 2 & 0 \\ -3 & 5 & 2 \end{pmatrix}$. Then either by solving the characteristic polynomial or observing that this is triangular (Theorem 73), the eigenvalues are 1, 2. Solving the linear systems, $\lambda = 1, (\lambda \mathbb{1} - A)x = 0$

with general solution $\begin{pmatrix} x \\ y \\ z \end{pmatrix} = t \begin{pmatrix} 1 \\ -1 \\ 8 \end{pmatrix}$, see that $E_1 = \text{span} \left\{ \begin{pmatrix} 1 \\ -1 \\ 8 \end{pmatrix} \right\}$. Next, solving the linear

system $\lambda = 2, (\lambda \mathbb{1} - A)x = 0$ with general solutions $\begin{pmatrix} x \\ y \\ z \end{pmatrix} = t \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}$, see that $E_2 = \text{span} \left\{ \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \right\}$.

We only have two linearly independent eigenvectors, therefore A is not diagonalizable by Theorem 74.

Exercise 67. Let A be square matrix order n , then suppose we have $m < n$ linearly independent eigenvectors $u_i, i \in [m]$, where $Au_i = \lambda_i u_i$, and λ_i 's are not necessarily distinct. For new eigenvalue $\mu \neq \lambda_{i \in [m]}$, and linearly independent vectors $\{v_j, j \in [p]\} \subseteq E_\mu$, prove $\{u_i, i \in [m]\} \cup \{v_j, j \in [p]\}$ is linearly independent.

Proof. Consider $\sum_i^m a_i u_i + \sum_j^p b_j v_j = 0$, then multiply A to both sides to get

$$\sum_i^m a_i \lambda_i u_i + \sum_j^p b_j \mu v_j = 0, \quad (312)$$

and subtract the two equations $\sum_i^m a_i \lambda_i u_i + \sum_j^p b_j \mu v_j = 0$ and $\mu \cdot \left(\sum_i^m a_i u_i + \sum_j^p b_j v_j = 0 \right)$ to get

$$\sum_i^m a_i (\lambda_i - \mu) u_i = 0, \quad (313)$$

which implies $a_i (\lambda_i - \mu) = 0$ by independence of u_i 's, But $\lambda_i \neq \mu$, so each of the a_i 's = 0. Substitute this into the vector equations to get $\sum_j^p b_j v_j = 0$, which by the linear independence of v_j 's, imply each of b_j 's = 0. \square

Exercise 68. Prove that eigenvectors belonging to distinct eigenspaces are linearly independent.

Proof. Let $Tv_1 = \lambda_1 v_1, Tv_2 = \lambda_2 v_2$ and $\lambda_1 \neq \lambda_2$. Then consider $\alpha_1 v_1 + \alpha_2 v_2 = 0$, then

$$0 = T(0) = T(\alpha_1 v_1 + \alpha_2 v_2) = \alpha_1 \lambda_1 v_1 + \alpha_2 \lambda_2 v_2 \quad (314)$$

by linear transformation properties (Theorem 76), and see that $\lambda_1 0 = \lambda_1 \alpha_1 v_1 + \lambda_1 \alpha_2 v_2$. Since

$$0 = \alpha_1 \lambda_1 v_1 + \alpha_2 \lambda_2 v_2 = \alpha_1 \lambda_1 v_1 + \alpha_2 \lambda_1 v_2, \quad (315)$$

$0 = 0v_1 + \alpha_2(\lambda_2 - \lambda_1)v_2$ see that $\alpha_2 = 0$ since $\lambda_1 \neq \lambda_2$ by assumption and $v_2 \neq 0$ by definition of eigenvectors (Definition 79). Then $0 = \alpha_1 v_1 + 0v_2 \implies \alpha_1 = 0$ since $v_1 \neq 0$ by definition of eigenvector, and $\alpha_1 = \alpha_2 = 0$. For two eigenvectors, consider them already independent and belonging to the same eigenspace, or if they belong to distinct eigenspaces, we have shown they must be linearly independent. Then the induction proof is shown in Exercise 67 and the result generalizes to any set of eigenvectors each from distinct eigenspaces. \square

Corollary 6. *Let A be square matrix order n . If A has n distinct eigenvalues, then A is diagonalizable.*

Proof. This is trivial to see, since for each eigenvalue, there is at least one eigenvector associated with it. We have n eigenvectors. The eigenvectors are linearly independent by Exercise 68, hence by Theorem 74, A is diagonalizable. \square

See that for diagonalizable matrix A of square matrix order n and invertible P satisfying

$$P^{-1}AP = D, \quad (316)$$

where D is diagonal matrix with diagonal entry λ_i at $D_{ii}, i \in [n]$, we have

1. for $m \in \mathbb{Z}^+, A^m = PD^m P^{-1}$, where D^m is diagonal matrix with diagonal entry λ_i^m at (i, i) entry,
2. and if we are further given that A^{-1} exists, then $\lambda_i \neq 0$ for all i by Theorem 72 and λ_i^{-1} is valid for all $i \in [n]$. In fact

$$A^{-1} = P\tilde{D}P^{-1} \quad (317)$$

where \tilde{D} is diagonal matrix with (i, i) entry λ_i^{-1} . We may also obtain A^{-m} as we did in part 1 by making the substitution $A^{-1} \rightarrow A, \tilde{D} \rightarrow D$.

Exercise 69. *Find a closed form solution for the Fibonacci sequence.*

Proof. The Fib-sequence may be written as (a_0, a_1, \dots) s.t. $a_0 = 0, a_1 = 1$ and $a_n = a_{n-1} + a_{n-2}$ for all $n \geq 2$. Then see that we may write

$$a_n = a_n \quad (318)$$

$$a_{n+1} = a_{n-1} + a_n, \quad (319)$$

with matrix representation

$$\begin{pmatrix} a_n \\ a_{n+1} \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} a_{n-1} \\ a_n \end{pmatrix}. \quad (320)$$

Define $x_n = \begin{pmatrix} a_n \\ a_{n+1} \end{pmatrix}, A = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}$, s.t. $x_n = Ax_{n-1} = A^2x_{n-2} = \dots = A^n x_0$. Then obtain an invertible

P as in Exercise 65, and get $P = \begin{pmatrix} 1 & 1 \\ \frac{1+\sqrt{5}}{2} & \frac{1-\sqrt{5}}{2} \end{pmatrix}$. Compute $P^{-1}AP = D = \begin{pmatrix} \frac{1+\sqrt{5}}{2} & 0 \\ 0 & \frac{1-\sqrt{5}}{2} \end{pmatrix}$. Then

we may write

$$\begin{pmatrix} a_n \\ a_{n+1} \end{pmatrix} = x_n = A^n x_0 \quad (321)$$

$$= \begin{pmatrix} 1 & 1 \\ \frac{1+\sqrt{5}}{2} & \frac{1-\sqrt{5}}{2} \end{pmatrix} \begin{pmatrix} \left(\frac{1+\sqrt{5}}{2}\right)^n & 0 \\ 0 & \left(\frac{1-\sqrt{5}}{2}\right)^n \end{pmatrix} \begin{pmatrix} 1 & 1 \\ \frac{1+\sqrt{5}}{2} & \frac{1-\sqrt{5}}{2} \end{pmatrix}^{-1} \begin{pmatrix} 0 \\ 1 \end{pmatrix} \quad (322)$$

$$= \begin{pmatrix} \frac{1}{\sqrt{5}} \left(\frac{1+\sqrt{5}}{2}\right)^n - \frac{1}{\sqrt{5}} \left(\frac{1-\sqrt{5}}{2}\right)^n \\ \frac{1}{\sqrt{5}} \left(\frac{1+\sqrt{5}}{2}\right)^{n+1} - \frac{1}{\sqrt{5}} \left(\frac{1-\sqrt{5}}{2}\right)^{n+1} \end{pmatrix}. \quad (323)$$

We have found the n -th Fibonacci sequence number, a_n . \square

3.1.6.3 Orthogonal Diagonalization

If we have obtained linearly independent eigenvectors (see Exercise 65), we may obtain an orthonormal basis for the span of these eigenvectors (recall we may use Gram-Schmidt procedure to obtain an orthonormal set from a basis (Definition 61)).

Definition 83 (Orthogonally diagonalizable). *Square matrix A is orthogonally diagonalizable if there exists orthogonal matrix P s.t. $P'AP = D$, where D is some diagonal matrix. P is said to orthogonally diagonalize A .*

Theorem 75. *Square matrix A order n is orthogonally diagonalizable iff $A' = A$ (it is symmetric).*

Proof. We only prove \rightarrow . Suppose A is orthogonally diagonalizable, then for some P , $P'AP = D$ and $P' = P^{-1}$ with D being diagonal matrix. We may write

$$A = (P')^{-1}DP^{-1} = PDP'. \quad (324)$$

Since $D' = D$, we have

$$A' = (PDP')' = P''D'P' = PDP' = A. \quad (325)$$

Verify this theorem for \leftarrow . \square

Exercise 70. *Given symmetric matrix A order n , discuss how to find an orthogonal matrix P s.t. $P'AP = D$ for some diagonal matrix D .*

Proof. -

1. First, find all the distinct eigenvalues, $\lambda_i, i \in [k]$
2. For each λ_i , find basis S_{λ_i} spanning E_{λ_i} and use Gram-Schmidt process to obtain orthonormal basis T_{λ_i} .
3. Let $T = \cup_i^k T_{\lambda_i} := \{v_1, \dots, v_n\}$. Then $P = (v_1 v_2 \dots v_n)$ is orthogonal matrix that diagonalizes A .

\square

When the matrix is symmetric, it turns out that the eigenvalues are always real (verify this). By Result 4, let the characteristic polynomial be expressed

$$\det(\lambda \mathbb{1} - A) = \prod_i^k (\lambda - \lambda_i)^{r_i}, \quad (326)$$

then $\dim(E_{\lambda_i}) = r_i$ and $|S_{\lambda_i}| = |T_{\lambda_i}| = r_i$.

3.1.6.4 Quadratic Forms and Conic Sections

Definition 84 (Quadratic Form). *The general form*

$$Q(x_1, \dots, x_n) = \sum_{i=1}^n \sum_{j=i}^n q_{ij} x_i x_j, \quad (327)$$

where $q_{ij} \in \mathbb{R}$ is said to be a quadratic form in n variables $x_i, i \in [n]$. If we define symmetric matrix

$$A = (a_{ij}) \text{ where } a_{ij} = \begin{cases} q_{ii} & i = j, \\ \frac{1}{2}q_{ij} & i < j, \\ \frac{1}{2}q_{ji} & i > j, \end{cases} \quad (328)$$

then see that we may express

$$Q((x_i)_{i \in [n]}) = (x_1 \ x_2 \ \dots \ x_n) \begin{pmatrix} q_{11} & \frac{1}{2}q_{12} & \dots & \frac{1}{2}q_{1n} \\ \frac{1}{2}q_{12} & q_{22} & \dots & \frac{1}{2}q_{2n} \\ \dots & \dots & \dots & \dots \\ \frac{1}{2}q_{1n} & \frac{1}{2}q_{2n} & \dots & q_{nn} \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ \dots \\ x_n \end{pmatrix} = x'Ax. \quad (329)$$

Then we may write $Q : \mathbb{R}^n \rightarrow \mathbb{R}$, where $Q(x) = x'Ax$ for all $x \in \mathbb{R}^n$.

The quadratic form takes quite a common occurrence in practical applications. For instance, see multivariate normal density (Equation 700), factor hedging objectives (Equation 1309) and mean-variance portfolios (Equation 204).

Exercise 71. Consider the quadratic form $Q_2(x, y, z) = x^2 + 2y^2 + z^2 + 2xz$, see that we may write

$$Q_2(x, y, z) = \begin{pmatrix} x & y & z \end{pmatrix} \begin{pmatrix} 1 & 0 & 1 \\ 0 & 2 & 0 \\ 1 & 0 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix}. \quad (330)$$

Exercise 72 (Simplification of Quadratic Forms). Let $Q(x) = x'Ax$ be a quadratic form for $x' = (x_1 \ \dots \ x_n)$, and $n \times n$ symmetric matrix A . We would like to simplify the quadratic form. Since A is symmetric, apply algorithm in Exercise 70 to obtain orthogonal P s.t. $P'AP = D$, where D is diagonal matrix with (i, i) entry $\lambda_i, i \in [n]$. Next, define new variables $y_i, i \in [n]$ s.t. $y = P'x = P^{-1}x$. Then $x = Py$ and we may write

$$Q(x) = Q(Py) = (Py)'A(Py) = y'P'APy = y'Dy = \sum_i^n \lambda_i y_i^2. \quad (331)$$

Exercise 73. Consider again the quadratic form $Q_2(x, y, z) = x^2 + 2y^2 + z^2 + 2xz$ as in Exercise 71, then we perform simplification of this quadratic form as suggested in Exercise 72. By algorithm presented

in Exercise 70, obtain orthogonal matrix $P = \begin{pmatrix} \frac{1}{\sqrt{2}} & 0 & -\frac{1}{\sqrt{2}} \\ 0 & 1 & 0 \\ \frac{1}{\sqrt{2}} & 0 & \frac{1}{\sqrt{2}} \end{pmatrix}$. Then $P' \begin{pmatrix} 1 & 0 & 1 \\ 0 & 2 & 0 \\ 1 & 0 & 1 \end{pmatrix} P = \begin{pmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 0 \end{pmatrix}$.

Defining the variables

$$\begin{pmatrix} x' \\ y' \\ z' \end{pmatrix} = P' \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} \frac{1}{\sqrt{2}}(x+z) \\ y \\ \frac{1}{\sqrt{2}}(-x+z) \end{pmatrix}. \quad (332)$$

Then we may write the quadratic form

$$Q_2(x, y, z) = (x' \ y' \ z') \begin{pmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} x' \\ y' \\ z' \end{pmatrix} = 2x'^2 + 2y'^2 = (x+z)^2 + 2y^2. \quad (333)$$

Definition 85 (Quadratic Equation and Associated Quadratic Forms). A quadratic equation in two variables x, y takes form

$$ax^2 + bxy + cy^2 + dx + ey = f, \quad (334)$$

where $a, b, c, d, e, f \in \mathbb{R}$ and $\exists, a, b, c \neq 0$. We may express

$$(x \ y) \begin{pmatrix} a & \frac{1}{2}b \\ \frac{1}{2}b & c \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + (d \ e) \begin{pmatrix} x \\ y \end{pmatrix} = f. \quad (335)$$

Denote

$$x = \begin{pmatrix} x \\ y \end{pmatrix}, \quad A = \begin{pmatrix} a & \frac{1}{2}b \\ \frac{1}{2}b & c \end{pmatrix}, \quad b = \begin{pmatrix} d \\ e \end{pmatrix}, \quad (336)$$

so that the quadratic equation is written $x'Ax + b'x = f$. The $x'Ax$ term (expanded, $ax^2 + bxy + cy^2$) is called a quadratic form associated with the quadratic equation.

A quadratic equation (Definition 85) represents graphically a conic section; a conic section is degenerated if it is empty set, point, line, pair of lines, and non-degenerated if it is circle, ellipse, hyperbola or parabola. A non-degenerated conic section is said to be standard form if it takes one of form in Table 3.1.

Table 3.1: Standard Forms for Conic Section

N-D Form	Equation	Quadratic Form
Circle/Ellipse	$\frac{x^2}{\alpha^2} + \frac{y^2}{\beta^2} = 1$	$(x \ y) \begin{pmatrix} \frac{1}{\alpha^2} & 0 \\ 0 & \frac{1}{\beta^2} \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = 1$
Hyperbola	$\frac{x^2}{\alpha^2} - \frac{y^2}{\beta^2} = 1$	$(x \ y) \begin{pmatrix} \frac{1}{\alpha^2} & 0 \\ 0 & -\frac{1}{\beta^2} \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = 1$
Hyperbola	$-\frac{x^2}{\alpha^2} + \frac{y^2}{\beta^2} = 1$	$(x \ y) \begin{pmatrix} -\frac{1}{\alpha^2} & 0 \\ 0 & \frac{1}{\beta^2} \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = 1$
Parabola	$x^2 = \alpha y$	$(x \ y) \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + (0 \ -\alpha) \begin{pmatrix} x \\ y \end{pmatrix} = 0$
Parabola	$y^2 = \alpha x$	$(x \ y) \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + (-\alpha \ 0) \begin{pmatrix} x \\ y \end{pmatrix} = 0$

Exercise 74. Consider the quadratic equation $2x^2 + 24xy + 9y^2 + 20x - 6y = 5$. Show this can be written as standard form of hyperbola.

Proof. The quadratic equation may be written

$$(x \ y) \begin{pmatrix} 2 & 12 \\ 12 & 9 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + (20 \ -6) \begin{pmatrix} x \\ y \end{pmatrix} = 5. \quad (337)$$

Obtain orthogonal matrix $P = \begin{pmatrix} \frac{3}{5} & -\frac{4}{5} \\ \frac{4}{5} & \frac{3}{5} \end{pmatrix}$ s.t. $P' \begin{pmatrix} 2 & 12 \\ 12 & 9 \end{pmatrix} P = \begin{pmatrix} 18 & 0 \\ 0 & -7 \end{pmatrix} = D$. Define $\begin{pmatrix} x' \\ y' \end{pmatrix} = P' \begin{pmatrix} x \\ y \end{pmatrix}$, then the quadratic equation becomes

$$(x' \ y')D \begin{pmatrix} x' \\ y' \end{pmatrix} + \begin{pmatrix} 20 & -6 \end{pmatrix} \begin{pmatrix} \frac{3}{5} & -\frac{4}{5} \\ \frac{4}{5} & \frac{3}{5} \end{pmatrix} \begin{pmatrix} x' \\ y' \end{pmatrix} = 5. \quad (338)$$

Then

$$18x'^2 - 7y'^2 + \frac{36}{5}x' - \frac{98}{5}y' = 5 \quad (339)$$

$$18(x' + \frac{1}{5})^2 - 7(y' + \frac{7}{5})^2 = -8 \quad (340)$$

$$-\frac{(x' + \frac{1}{5})^2}{4/9} + \frac{(y' + \frac{7}{5})^2}{8/7} = 1. \quad (341)$$

□

Exercise 75. Let A be square matrix order 2, and assume characteristic polynomial $\lambda^2 + m\lambda + n$. Then show that $m = -\text{tr}(A)$ (Definition 41), $n = \det(A)$.

Proof. Define arbitrary matrix $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$, then

$$\det(\lambda \mathbb{1} - A) = \begin{vmatrix} \lambda - a & -b \\ -c & \lambda - d \end{vmatrix} = (\lambda - a)(\lambda - d) - (-b)(-c) = \lambda^2 + (-a - d)\lambda + (ad - bc). \quad (342)$$

Then $m = -a - d = -\text{tr}(A)$, the negative sum of diagonals in A and $n = \det(A)$. □

Exercise 76. Let λ be eigenvalue of square matrix A , then

1. show λ^n is eigenvalue of A^n , where $n \in \mathbb{Z}^+$,
2. if A invertible, show $\frac{1}{\lambda}$ is eigenvalue of A^{-1} .
3. show λ is eigenvalue of A' .

Proof. -

1. We prove by induction. For $j = 1$, $A^j x = \lambda x$. Assume for $j < n$, that $A^j x = \lambda^j x$. Then for $j + 1$, see $A^{j+1} x = AA^j x = A\lambda^j x = \lambda^{j+1} x$. By induction we are done.
2. Let x be eigenvector associated with λ , then $Ax = \lambda x \implies x = A^{-1}(\lambda x) = \lambda A^{-1}x$, which implies $\frac{1}{\lambda}x = A^{-1}x$.
3. We prove using the transpose-determinant relation. λ is eigenvalue of A if it satisfies characteristic equation $\det(\lambda \mathbb{1} - A) = 0$. See $\det(\lambda \mathbb{1} - A) = \det((\lambda \mathbb{1} - A)') = \det(\lambda \mathbb{1} - A') = 0$, so λ is eigenvalue of A' .

□

Exercise 77. Let A be square matrix s.t $A^2 = A$, then

1. show that if A has eigenvalue λ , it must be either zero or one.

2. find the matrix size 2×2 (possibly many) A with eigenvalues zero and one.

Proof. -

1. Let x be eigenvector associated with λ , then $A^2 = A \implies A^2x = Ax \implies \lambda^2x = \lambda x \implies \lambda(\lambda - 1)x = 0$.

2. Since A has two distinct eigenvalues, $\exists P = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ s.t. $P^{-1}AP = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$, and using the classical adjoint, write (Theorem 23)

$$P^{-1} = \frac{1}{\det(P)} \begin{pmatrix} d & -c \\ -b & a \end{pmatrix}' \quad \text{s.t.} \quad (343)$$

$$A = P \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} P^{-1} = \frac{1}{\det(P)} \begin{pmatrix} a & 0 \\ c & 0 \end{pmatrix} \begin{pmatrix} d & -b \\ -c & a \end{pmatrix} = \frac{1}{\det(P)} \begin{pmatrix} ad & -ab \\ cd & -cb \end{pmatrix}. \quad (344)$$

We require that $\det(P) = ad - bc \neq 0$.

□

Exercise 78. Let A be square matrix order n , $A^2 = 0$ but $A \neq 0$. Then

1. show that the only possible eigenvalue is 0,
2. argue if A is diagonalizable or not,
3. for $u \in \mathbb{R}^n$, $Au \neq 0$, prove (u, Au) linearly independent,
4. for $n = 2$, \exists invertible P satisfying $P^{-1}AP = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$.

Proof. -

1. For $x \neq 0$, $Ax = \lambda x$, see that $A^2 = 0 \implies A^2x = 0x \implies A(\lambda x) = 0 \implies \lambda^2x = 0$ iff $\lambda = 0$.

2. Not diagonalizable, since if it is, $\exists P$ s.t. $P^{-1}AP = 0$, $A = P0P^{-1} = 0$ but $A \neq 0$.

3. Consider $au + bAu = 0 \implies A(au + Au) = A0 \implies aAu + A^2u = 0 \implies aAu = 0$, but $Au \neq 0$ so $a = 0$. Then $bAu = 0$ but $Au \neq 0$ so $b = 0$. So $a, b = 0$ and we are done.

4. We show by construction. Let $P = \begin{pmatrix} u & Au \end{pmatrix}$, which is invertible by Theorem 72 and see $AP = \begin{pmatrix} Au & A^2u \end{pmatrix} = \begin{pmatrix} Au & 0 \end{pmatrix}$. Also, $P \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} 0u + Au & 0u + 0Au \end{pmatrix} = \begin{pmatrix} Au & 0 \end{pmatrix}$. Then $AP = P \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$ and the result follows.

□

Exercise 79. Let $\{u_i, i \in [n]\}$ be basis spanning \mathbb{R}^n , and A be square matrix order n satisfying $Au_i = u_{i+1}$ for $i \in [n-1]$, $Au_n = 0$. Show the only possible eigenvalue of $A = 0$, and find all the associated eigenvectors.

Proof.

$$\forall i \in [n], \quad A^n u_i = A^{n-1} u_{i+1} = \dots = A^i u_n = 0. \quad (345)$$

For $v \in \mathbb{R}^n$ where $Av = \lambda v$ and $v = \sum_i^n c_i u_i$, we can write

$$A^n v = \sum_i^n c_i A^n u_i = 0. \quad (346)$$

Since $A^n v = \lambda^n v$ (see Exercise 76) but $v \neq 0, \lambda = 0$ and the eigenvalue must be zero. To get all the eigenvectors, write

$$0 = Av = \sum_{i=1}^n c_i A u_i = \sum_{i=1}^{n-1} c_i u_{i+1} + c_n 0. \quad (347)$$

All u_2, \dots, u_n are linearly independent, so c_i 's are zero for $i \in [n-1]$ and $v = c_n u_n$. The eigenvectors are just vectors in $\text{span}\{u_n\}$. \square

Exercise 80. Determine the values of a, b s.t. $\begin{pmatrix} a & 1 \\ 0 & b \end{pmatrix}$ is diagonalizable.

Proof. Consider the characteristic equation

$$\begin{vmatrix} \lambda - a & -1 \\ 0 & \lambda - b \end{vmatrix} = 0 \Leftrightarrow (\lambda - a)(\lambda - b) = 0. \quad (348)$$

Then the eigenvalues are a and b . If $a = b$, then consider the HLS $\begin{pmatrix} \lambda - a & -1 \\ 0 & \lambda - a \end{pmatrix} x = 0$, with $\lambda = a$, which would clearly have nullspace spanned by a single vector. Then the matrix is not diagonalizable. Otherwise, we have two distinct eigenvalues, and by Corollary 6, the matrix is diagonalizable. \square

Exercise 81. Square matrices A, B are similar if $\exists P$ s.t. $P^{-1}AP = B$. If A, B similar, then prove the following statements hold true.

1. A^n, B^n similar $\forall n \in \mathbb{Z}^+$.
2. If A invertible, B invertible and A^{-1}, B^{-1} similar.
3. If A diagonalizable, B diagonalizable.

Proof. -

1. $B^n = (P^{-1}AP)(P^{-1}AP) \dots (P^{-1}AP) = P^{-1}A^n P$.
2. $B^{-1} = (P^{-1}AP)^{-1} = P^{-1}A^{-1}P$.
3. If $\exists Q$ s.t. $Q^{-1}AQ = D$, define $R = P^{-1}Q$, then R is invertible (Theorem 14) and $R^{-1}BR = Q^{-1}PBP^{-1}Q = Q^{-1}AQ = D$.

\square

Exercise 82. A square matrix A order n is stochastic matrix if all entries are ≥ 0 and the sum of entries in each column is one. Show that 1 is eigenvalue of a stochastic matrix and for any eigenvalue λ , $|\lambda| \leq 1$.

Proof. See that for stochastic matrix A , for all $i \in [n]$, $\sum_j^n a_{ji} = 1$. Then $A' \begin{pmatrix} 1 & 1 & \dots & 1 \end{pmatrix}' = \begin{pmatrix} 1 & 1 & \dots & 1 \end{pmatrix}'$. Recall that one is eigenvalue of A' iff it is eigenvalue of A (Exercise 76). For the second assertion, suppose $A'x = \lambda x$ for some $x \neq 0$. For $k = \arg \max |x_j|, j \in [n]$, see that $|x_k| > 0$ since $x \neq 0$. Define the access operator $[\cdot]$ s.t. $a[i]$ accesses the value at i -th coordinate of a . Then

$$(A'x)[k] = \sum_i^n a_{ik}x_i = \lambda x_k \implies |\lambda||x_k| = \left| \sum_i^n a_{ik}x_i \right| \leq \sum_i^n |a_{ik}x_i| \leq \sum_i^n a_{ik}|x_i| \leq \left(\sum_i^n a_{ik} \right) |x_k| = |x_k|.$$

We used the triangle inequality (Exercise 69) and property $a_{ij} \geq 0$. The statement implies $|\lambda| \leq 1$. \square

Exercise 83 (Matrix Exponentiation). *Let A be square matrix, then exponential for A is the matrix*

$$\exp(A) = \mathbb{1} + A + \frac{1}{2!}A^2 + \dots = \sum_{n=1}^{\infty} \frac{1}{n!}A^n. \quad (349)$$

Compute $\exp(A)$ for $A = \begin{pmatrix} 3 & 0 \\ 8 & -1 \end{pmatrix}$.

Proof. Obtain matrix $P^{-1}AP = \begin{pmatrix} 2 & 0 \\ 0 & 4 \end{pmatrix}$ for $P = \begin{pmatrix} -1 & 1 \\ 1 & 1 \end{pmatrix}$. Then $A^n = P \begin{pmatrix} 2^n & 0 \\ 0 & 4^n \end{pmatrix} P^{-1}$ and

$$\exp(A) = P \begin{pmatrix} 1 + \frac{1}{1!}2 + \frac{1}{2!}2^2 + \dots & 0 \\ 0 & 1 + \frac{1}{1!}4 + \frac{1}{2!}4^2 + \dots \end{pmatrix} P^{-1} \quad (350)$$

using the Taylor expansions $\exp(x) = \sum_{n=0}^{\infty} \frac{1}{n!}x^n$. \square

Exercise 84. *Determine which are true:*

1. *A diagonalizable implies A' diagonalizable.*
2. *A, B diagonalizable implies $A + B$ diagonalizable.*
3. *A, B diagonalizable implies AB diagonalizable.*

Proof. -

1. True, since for $P^{-1}AP = D$ we can write

$$D = D' = (P^{-1}AP)' = P'A'(P^{-1})' = P'A'(P')^{-1}. \quad (351)$$

2. False by counterexample $A = \begin{pmatrix} 2 & 0 \\ 0 & 0 \end{pmatrix}, B = \begin{pmatrix} 0 & 0 \\ 1 & 2 \end{pmatrix}$.

3. False by counterexample $A = \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix}, B = \begin{pmatrix} 1 & 0 \\ 1 & 2 \end{pmatrix}$.

\square

Exercise 85. *Let u be some column matrix, then show that $\mathbb{1} - uu'$ is orthogonally diagonalizable.*

Proof. $(uu')' = uu' \implies (\mathbb{1} - uu') = (\mathbb{1} - uu')'$ (it is symmetric). \square

Exercise 86. *Let A be symmetric matrix, if $Au = \lambda u, Av = \mu v, \lambda \neq \mu$, show that $u \cdot v = 0$.*

Proof. $v' Au = v'(\lambda u) = \lambda v' u = \lambda(v \cdot u)$ and by symmetricity $v' Au = v' A' u = (Av)' u = (\mu v)' u = \mu v' u = \mu(v \cdot u)$ implies $\lambda(v \cdot u) = \mu(v \cdot u) \implies (\lambda - \mu)(v \cdot u)$ implies $v \cdot u = 0$ since $\lambda \neq \mu$. \square

Exercise 87. Determine which are true: If A, B orthogonally diagonalizable,

1. then $A + B$ orthogonally diagonalizable.
2. then AB orthogonally diagonalizable.

Proof. -

1. True, since A, B orthogonally diagonalizable iff $A = A', B = B'$ implies $A + B = A' + B' = (A + B)'$.

2. False by counterexample $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, B = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$.

\square

Exercise 88. Let there be real constants $\lambda_1 \leq \lambda_2 \leq \lambda_3$. Then

1. Show λ_1 is the minimum value of $\sum_i^3 \lambda_i x_i^2$ for all real numbers x_1, x_2, x_3 satisfying $\sum_i^3 x_i^2 = 1$.
2. Show λ_3 is the maximum value satisfying conditions in part 1.

3. Find the minimum and maximum values of $u' Qu$ for all vectors u in \mathbb{R}^3 where $Q = \begin{pmatrix} 2 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -1 & 2 \end{pmatrix}$

with constraint $\|u\| = 1$.

Proof. -

1. See that if we define $(x_1, x_2, x_3) = (1, 0, 0)$, then $\sum_i^3 x_i^2 = 1, \sum_i^n \lambda_i x_i^2 = \lambda_1$. The minimum value must be $\leq \lambda_1$. On the other hand, if $\sum_i^3 x_i^2 = 1, \sum_i^3 \lambda_i x_i^2 \geq \sum_i^3 \lambda_1 x_i^2 = \lambda_1(\sum_i^3 x_i^2) = \lambda_1$. The result follows.

2. The second part follows by the same technique as in part 1.

3. Solve for eigenvalues of Q to obtain $2 - \sqrt{2}, 2, 2 + \sqrt{2}$. Then $\exists P$ s.t $P'QP = D$ where D is diagonal matrix with diagonal entries $2 - \sqrt{2}, 2, 2 + \sqrt{2}$. Define $P'u = (x_1, x_2, x_3)'$, then

$$u' Qu = u'(PP')Q(PP')u = (P'u)'(P'QP)(P'u) = (2 - \sqrt{2})x_1^2 + 2x_2^2 + (2 + \sqrt{2})x_3^2 \quad (352)$$

and $u'u = u'(PP')u = (P'u)'(P'u) = \sum_i^3 x_i^2$. The minimum value is $2 - \sqrt{2}$ and maximum value $2 + \sqrt{2}$.

\square

Exercise 89. Name the conic section and write the standard form represented by a non-degenerated conic section satisfying

$$(x \ y)A \begin{pmatrix} x \\ y \end{pmatrix} \quad (353)$$

where A is symmetric matrix order 2 with eigenvalues 1, 4.

Proof. There exists orthogonal P s.t. $P'AP = D$ with diagonal entries 1, 4. Define $\begin{pmatrix} x' \\ y' \end{pmatrix} = P' \begin{pmatrix} x \\ y \end{pmatrix}$, then

$$\begin{pmatrix} x & y \end{pmatrix} A \begin{pmatrix} x \\ y \end{pmatrix} = 8 \leftrightarrow \begin{pmatrix} x' & y' \end{pmatrix} P'AP \begin{pmatrix} x' \\ y' \end{pmatrix} = 8 \leftrightarrow \frac{x'^2}{8} + \frac{y'^2}{2} = 1. \quad (354)$$

This is ellipse (see Table 3.1). □

3.1.7 Linear Transformations

Definition 86. A linear transformation is a mapping $T : \mathbb{R}^n \rightarrow \mathbb{R}^m$ of form

$$T = \left(\begin{pmatrix} x_1 \\ x_2 \\ \dots \\ x_n \end{pmatrix} \right) = \underbrace{\begin{pmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & \dots & \dots & a_{2n} \\ \dots & \dots & \dots & \dots \\ a_{m1} & a_{m2} & \dots & a_{mn} \end{pmatrix}}_A \begin{pmatrix} x_1 \\ x_2 \\ \dots \\ x_n \end{pmatrix}, \quad (355)$$

where $a_{ij} \in \mathbb{R}$ for $i \in [m], j \in [n]$. A is called the standard matrix. When T is mapping from $\mathbb{R}^n \rightarrow \mathbb{R}^n$, then it is called a linear operator. For brevity, if we wish to indicate the dimension of the domain and images under T , we notate

$$T \text{ is linear transformation from } \mathbb{R}^n \rightarrow \mathbb{R}^m \equiv T_n^{(m)}. \quad (356)$$

In abstract linear algebra, we define $T : V \rightarrow W$ to be a mapping from vector space V to W , and say it is linear transformation if $\forall u, v \in V, c, d \in \mathbb{R}, T(cu + dv) = cT(u) + dT(v)$ is satisfied.

An example of a linear transformation is the identity transformation $I : \mathbb{R}^n \rightarrow \mathbb{R}^n$ s.t. $I(u) = u$ for all $u \in \mathbb{R}^n$. The standard matrix is $\mathbb{1}$. Another is the zero transformation $O : \mathbb{R}^n \rightarrow \mathbb{R}^m$ s.t. $O(u) = 0$ for all $u \in \mathbb{R}^n$. The standard matrix is $0_{m \times n}$.

Suppose we have linear transformation $T : \mathbb{R}^2 \rightarrow \mathbb{R}^3$ s.t.

$$T \left(\begin{pmatrix} x \\ y \end{pmatrix} \right) = \begin{pmatrix} x + y \\ 2x \\ -3y \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 2 & 0 \\ 0 & -3 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} \quad \forall \begin{pmatrix} x \\ y \end{pmatrix} \in \mathbb{R}^2. \quad (357)$$

See that standard matrix is $\begin{pmatrix} 1 & 1 \\ 2 & 0 \\ 0 & -3 \end{pmatrix}$.

Theorem 76. Let $T = \mathbb{R}^n \rightarrow \mathbb{R}^m$ be linear transformation,

1. $T(0) = 0$,
2. $\forall u_i \in \mathbb{R}^n, c_i \in \mathbb{R}$,

$$T\left(\sum_i^k c_i u_i\right) = \sum_i^k c_i T(u_i). \quad (358)$$

Proof. Let A be standard matrix for T , then $T(u) = Au$ by definition for $u \in \mathbb{R}^n$ and we may apply the properties of matrix operations. In particular, $T(0) = A0 = 0$, $T(\sum c_i u_i) = A(\sum c_i u_i) = \sum c_i Au_i = \sum c_i T(u_i)$ by Theorem 6. □

We may use Theorem 76 to check if a function given is a linear transformation or not.

Exercise 90. Show that $T_n^{(m)}$ is linear transformation iff $T(cu + dv) = cT(u) + dT(v)$ for all $u, v \in \mathbb{R}^n$, $c, d \in \mathbb{R}$.

Proof. \rightarrow : follows immediately from Theorem 76. \leftarrow : suppose $\forall u, v \in \mathbb{R}^n$ and $c, d \in \mathbb{R}$, we have $T(cu + dv) = cT(u) + dT(v)$. Let $\{e_i, i \in [n]\}$ be basis for \mathbb{R}^n and $A = \begin{pmatrix} T(e_1) & \cdots & T(e_n) \end{pmatrix}$. For arbitrary $u \in \mathbb{R}^n$, we may express $u = \sum_i^n u_i e_i$, see that

$$T(u) = \sum_i^n u_i T(e_i) = \begin{pmatrix} T(e_1) & \cdots & T(e_n) \end{pmatrix} \begin{pmatrix} u_1 \\ u_2 \\ \vdots \\ u_n \end{pmatrix} = Au, \quad (359)$$

so T is linear transformation. □

Let $\{u_i, i \in [n]\}$ be basis spanning \mathbb{R}^n , then $\forall v \in \mathbb{R}^n$, see that we may write $v = \sum_i^n c_i u_i$, and by Theorem 76, $T(v) = \sum_i^n c_i T(u_i)$. It follows that the image $T(v)$ of v is determined completely by the images $T(u_i)$'s of basis vectors u_i .

Exercise 91. Let $T : \mathbb{R}^3 \rightarrow \mathbb{R}^2$ be linear transformation

$$T \left(\begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} \right) = \begin{pmatrix} 1 \\ 3 \end{pmatrix}, \quad T \left(\begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix} \right) = \begin{pmatrix} -1 \\ 2 \end{pmatrix}, \quad T \left(\begin{pmatrix} 2 \\ 0 \\ -1 \end{pmatrix} \right) = \begin{pmatrix} 4 \\ -1 \end{pmatrix}. \quad (360)$$

Then

1. find the image of vector $\begin{pmatrix} -1 \\ 4 \\ 6 \end{pmatrix}$ under T and

2. find formula representing T .

Proof. The vectors $\{(1, 1, 1)', (0, 1, 1)', (2, 0, -1)'\}$ are basis for \mathbb{R}^3 . Writing $(-1, 4, 6)'$ as l.c of the elements in the basis, solve for the linear system

$$\begin{pmatrix} -1 \\ 4 \\ 6 \end{pmatrix} = c_1 \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} + c_2 \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix} + c_3 \begin{pmatrix} 2 \\ 0 \\ -1 \end{pmatrix}. \quad (361)$$

The solution yields $c_1 = 3, c_2 = 1, c_3 = -2$, and therefore the image is

$$\begin{aligned} T \left(\begin{pmatrix} -1 \\ 4 \\ 6 \end{pmatrix} \right) &= T \left(3 \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} + \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix} - 2 \begin{pmatrix} 2 \\ 0 \\ -1 \end{pmatrix} \right) \\ &= 3T \left(\begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} \right) + T \left(\begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix} \right) - 2T \left(\begin{pmatrix} 2 \\ 0 \\ -1 \end{pmatrix} \right) = 3 \begin{pmatrix} 1 \\ 3 \end{pmatrix} + \begin{pmatrix} -1 \\ 2 \end{pmatrix} - 2 \begin{pmatrix} 4 \\ -1 \end{pmatrix} = \begin{pmatrix} -6 \\ 13 \end{pmatrix}. \end{aligned} \quad (362)$$

We repeat the steps in part 1, except on arbitrary vector in \mathbb{R}^3 . Solve $(x, y, z) = c_1(1, 1, 1) + c_2(0, 1, 1) + c_3(2, 0, -1)$ to get solution $c_1 = x - 2y + 2z$, $c_2 = -x + 3y - 2z$ and $c_3 = y - z$. Then the general formula is

$$T\left(\begin{pmatrix} x \\ y \\ z \end{pmatrix}\right) = (x - 2y + 2z)\begin{pmatrix} 1 \\ 1 \\ 3 \end{pmatrix} + (-x + 3y - 2z)\begin{pmatrix} -1 \\ 1 \\ 2 \end{pmatrix} + (y - z)\begin{pmatrix} 4 \\ -1 \\ -1 \end{pmatrix} = \begin{pmatrix} 2x - y \\ x - y + 3z \end{pmatrix}. \quad (363)$$

□

From the previous exercise, it follows that for $T : \mathbb{R}^n \rightarrow \mathbb{R}^m$, standard basis $\{e_i, i \in [n]\}$ (Definition 56), we have $T(e_i) = Ae_i$ as column i of the standard matrix. The images $T(e_i)$ for $i \in [n]$ completely define T .

Exercise 92 (Obtaining standard matrix via Gauss Jordan Elimination). *Consider the linear transformation in Exercise 91 - here we obtain the standard matrix directly via GJE (Theorem 5). Take*

$$\left[\begin{array}{ccc|ccc} 1 & 0 & 2 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 & 1 & 0 \\ 1 & 1 & -1 & 0 & 0 & 1 \end{array} \right] \rightarrow \left[\begin{array}{ccc|ccc} 1 & 0 & 0 & 1 & -2 & 2 \\ 0 & 1 & 0 & -1 & 3 & -2 \\ 0 & 0 & 1 & 0 & 1 & -1 \end{array} \right]. \quad (364)$$

Then each of the basis elements are written as l.c

$$\begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} - \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}, \quad \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} = -2 \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} + 3 \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix} + \begin{pmatrix} 2 \\ 0 \\ -1 \end{pmatrix}, \quad \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} = 2 \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} - 2 \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix} - \begin{pmatrix} 2 \\ 0 \\ -1 \end{pmatrix} \quad (365)$$

Then $T((1, 0, 0)') = T((1, 1, 1)') - T((0, 1, 1)') = (1, 3)' - (-1, 2)' = (2, 1)'$ and so on, and the standard matrix is just $(T(e_1) \ T(e_2) \ T(e_3))$.

Definition 87. Let $S : \mathbb{R}^n \rightarrow \mathbb{R}^m$, $T : \mathbb{R}^m \rightarrow \mathbb{R}^k$ be linear transformations. Then define the composition of T with S , $T \circ S$ as mapping $\mathbb{R}^n \rightarrow \mathbb{R}^k$ that satisfies

$$(T \circ S)(u) = T(S(u)) \quad u \in \mathbb{R}^n. \quad (366)$$

Theorem 77. If we have $S_n^{(m)}, T_m^{(k)}$, then $(T \circ S)_n^{(k)}$, that is $T \circ S$ is linear transformation $\mathbb{R}^n \rightarrow \mathbb{R}^k$. If A, B is standard matrix for $S_n^{(m)}, T_m^{(k)}$, then standard matrix for $(T \circ S)_n^{(k)}$ is BA .

Proof. For $u \in \mathbb{R}^n$, then $(T \circ S)(u) = T(S(u)) = T(Au) = BAu$. $T \circ S$ is linear transformation with standard matrix BA . □

3.1.7.1 Ranges and Kernels

Definition 88. For $T_n^{(m)}$, denote $R(T)$ as the range of T , and this is the set of images of T ,

$$R(T) = \{T(u) \mid u \in \mathbb{R}^n\} \subseteq \mathbb{R}^m. \quad (367)$$

Theorem 78. Let $T_n^{(m)}$ and $\{u_i, i \in [n]\}$ be basis for \mathbb{R}^n . Then recall that $T(v := \sum_i^n c_i v_i) \in \text{span}\{T(u_i), i \in [n]\}$ for all $v \in \mathbb{R}^n$ by Theorem 76. It follows that $R(T) \subseteq \text{span}\{T(u_i), i \in [n]\}$. On the other hand, see that $\forall i \in [n], \sum c_i T(u_i) = T(\sum c_i u_i) \in R(T)$ by Theorem 76, so $R(T) \supseteq \text{span}\{T(u_i), i \in [n]\}$. Then $R(T) = \text{span}\{T(u_i), i \in [n]\}$.

Theorem 79. Let A be standard matrix for $T_n^{(m)}$, then $R(T) = \text{colSpace}(A)$.

Proof. Let $\{e_i, i \in [n]\}$ be standard basis for \mathbb{R}^n , and since column i of A is $T(e_i)$, then by Theorem 78, $R(T) = \text{span}\{T(e_i), i \in [n]\} = \text{colSpace}(A)$. \square

Definition 89. Let T be linear transformation. Then $\dim(R(T))$ is called rank of T , and we denote this $\text{rank}(T)$. See that by Theorem 79, for standard matrix A of T , $\text{rank}(A) = \text{rank}(T)$.

Definition 90. Let $T_n^{(m)}$, then the kernel of T is denoted $\ker(T)$ and is the set of vectors in \mathbb{R}^n that maps to the zero vector in \mathbb{R}^m ,

$$\ker(T) = \{u | T(u) = 0\} \subseteq \mathbb{R}^n. \quad (368)$$

Theorem 80. For $T_n^{(m)}$ with standard matrix A , $\ker(T) = \text{nullSpace}(A)$.

Proof. See that $\ker(T) = \{u | T(u) = 0\} = \{u | Au = 0\}$, which by definition is the nullspace (Definition 64). \square

Definition 91. Let T be linear transformation, then $\dim(\ker(T))$ is called nullity of T and we denote this $\text{nullity}(T)$. See that for standard matrix A for T , $\text{nullity}(T) = \text{nullity}(A)$.

Theorem 81 (Rank-Nullity Theorem, Linear Transformations). It is trivial to see from reasoning in Theorem 51 that $\text{rank}(T) + \text{nullity}(T) = n$ for $T_n^{(m)}$.

Exercise 93. For T, T_1, T_2 linear transformations from $\mathbb{R}^n \rightarrow \mathbb{R}^m$ with standard matrices A, A, B respectively, define $(T_1 + T_2)_n^{(m)}$ s.t. $(T_1 + T_2)(u) = T_1(u) + T_2(u)$ for all $u \in \mathbb{R}^n$. Additionally, define $(\lambda T)_n^{(m)}$ s.t. $(\lambda T)(u) = \lambda T(u)$ for all $u \in \mathbb{R}^n$. Show that that $(T_1 + T_2), \lambda T$ are both linear transformations and find their standard matrices.

Proof. It is easy to see by the duality between a linear transformation and its standard matrix both results. That is, $(T_1 + T_2)(u) = T_1(u) + T_2(u) = Au + Bu = (A + B)u$, and $(\lambda T)(u) = \lambda T(u) = \lambda Au = (\lambda A)u$. \square

Exercise 94. Let $T_n^{(n)}$ be linear operator, and if $\exists S_n^{(n)}$ s.t. $S \circ T = \mathbb{1}$, the identity transformation, then T is said to be invertible with inverse S . For invertible T , standard matrix A , find standard matrix for inverse of T .

Proof. See $S(T(u)) = S(Au) = \mathbb{1}$ iff $S(Au) = A^{-1}(Au)$ so the standard matrix is A^{-1} for S . \square

Exercise 95. Let n be unit vector \mathbb{R}^n , and define $P_n^{(n)}$ s.t. $P(x) = x - (n \cdot x)n$ for all $x \in \mathbb{R}^n$. Then show that P is linear transformation, find its standard matrix and prove that $P \circ P = P$.

Proof. Note that the term $n \cdot x = n'x$ is 'commutative' since it is scalar.

$$\forall x \in \mathbb{R}^n, \quad P(x) = x - (n \cdot x)n = \mathbb{1}x - nn'x = (\mathbb{1} - nn')x, \quad (369)$$

so P is linear transformation with standard matrix $\mathbb{1} - nn'$. Next, write

$$(P \circ P)(x) = P(P(x)) = P(x - (n \cdot x)n) \quad (370)$$

$$= x - (n \cdot x)n - (n \cdot (x - (n \cdot x)n))n \quad (371)$$

$$= x - (n \cdot x)n - ((n \cdot x) - (n \cdot x)(n \cdot n))n \quad (372)$$

$$= x - (n \cdot x)n \quad (373)$$

$$= P(x). \quad (374)$$

\square

Exercise 96. Let $T_n^{(n)}$ be linear transformation and $T \circ T = T$.

1. If T is not zero transformation, show $\exists u \neq 0 \in \mathbb{R}^n$ s.t. $T(u) = u$.
2. If T is not identity transformation, show $\exists v \neq 0 \in \mathbb{R}^n$ s.t. $T(v) = 0$.
3. Find all linear transformations $T_n^{(n)}$ satisfying $T \circ T = T$.

Proof. -

1. Since T is not zero transformation, then $\exists x \in \mathbb{R}^n$ s.t. $T(x) \neq 0$, and defining $u = T(x)$, we have $T(u) = T(T(x)) = (T \circ T)(x) = T(x) = u$.
2. If T is not identity, then there exists $y \in \mathbb{R}^n$ s.t. $T(y) \neq y$. Then for $v = T(y) - y$,

$$T(v) = T(T(y) - y) = T(y) - T(y) = 0. \quad (375)$$

3. See Exercise 77.

□

Exercise 97. Let n be unit vector $\in \mathbb{R}^n$, and $F_n^{(n)}$ s.t. $F(x) = x - 2(n \cdot x)n$ for all $x \in \mathbb{R}^n$, then

1. show that F is linear transformation, and find its standard matrix.
2. prove $F \circ F = \mathbb{1}$, the identity transformation.
3. show that the standard matrix for F is orthogonal matrix.

Proof. -

- 1.

$$\forall x \in \mathbb{R}^n, \quad F(x) = x - 2(n \cdot x)n = \mathbb{1}x - 2nn'x = (\mathbb{1} - 2nn')x. \quad (376)$$

The standard matrix is $\mathbb{1} - 2nn'$.

2. Use the standard matrix and compute $(\mathbb{1} - 2nn')(\mathbb{1} - 2nn') = \mathbb{1} - 2nn' - 2nn' + 4n(n'n)n' = \mathbb{1}$.
3. See that $(\mathbb{1} - 2nn')$ is symmetric, and by part 2 we get $(\mathbb{1} - 2nn')'(\mathbb{1} - 2nn') = \mathbb{1}$.

□

Exercise 98. A linear operator $T_n^{(n)}$ is isometry of $\|T(u)\| = \|u\|$ for all $u \in \mathbb{R}^n$.

1. If T is isometry on \mathbb{R}^n , then show $T(u) \cdot T(v) = u \cdot v$ for all $u, v \in \mathbb{R}^n$.
2. Let A be standard matrix for linear operator $T_n^{(n)}$. Show T is isometry iff A is orthogonal matrix.

Proof. 1.

$$T(u + v) \cdot T(u + v) = (T(u) + T(v)) \cdot (T(u) + T(v)) \quad (377)$$

$$= T(u) \cdot T(u) + T(v) \cdot T(v) + 2(T(u) \cdot T(v)) \quad (378)$$

$$= \|T(u)\|^2 + \|T(v)\|^2 + 2(T(u) \cdot T(v)) \quad (379)$$

$$= \|u\|^2 + \|v\|^2 + 2(T(u) \cdot T(v)), \quad (380)$$

and

$$T(u+v) \cdot T(u+v) = \|T(u+v)\|^2 = \|u+v\|^2 = (u+v) \cdot (u+v) \quad (381)$$

$$= u \cdot u + v \cdot v + 2(u \cdot v) \quad (382)$$

$$= \|u\|^2 + \|v\|^2 + 2(u \cdot v). \quad (383)$$

2. $\|T(u)\| = \|Au\| = \|u\|$ (see Exercise 62). On the other hand, if T is isometry and $\{e_i, i \in [n]\}$ is standard basis (Definition 56), then $(Ae_i) \cdot (Ae_j) = (Ae_i)'Ae_j = e_i'A'Ae_j = (A'A)_{ij}$, but $(Ae_i)'Ae_j = T(e_i) \cdot T(e_j) = e_i \cdot e_j = \delta_{ij}$, so $A'A = \mathbf{1}$.

□

Exercise 99. Find the nullity of T given these information respectively:

1. $T_4^{(6)}$, $\text{rank}(T) = 2$.
2. $R(T_6^{(4)}) = \mathbb{R}^4$.
3. $RREF(T_6^{(6)})$ has four nonzero rows.

Proof. The nullity of T for part 1) is 2, part 2) is 2, and part 3) is 2. □

Exercise 100. Let $T_n^{(n)}$ be linear operator $T(v) = 2v$, then find the kernel and range of T .

Proof. The kernel is the zero space and range is \mathbb{R}^n . □

Exercise 101. Let V be subspace of \mathbb{R}^n , and define $P_n^{(n)}$ s.t. $\forall u \in \mathbb{R}^n$, $P(u)$ is projection u onto V (see Definition 77). Then show P is linear transformation. If $n = 3$, and V is plane $ax + by + cz = 0$, $\exists a, b, c \neq 0$, find $\ker(P)$, $R(P)$.

Proof. Let $\{v_i, i \in [k]\}$ be orthonormal basis spanning V , then by Theorem 58, we may express $P(u) = \sum_i^k (u \cdot v_i)v_i = (\sum_i^k v_i v_i')u$. $\ker(P) = \text{span}\{(a, b, c)\}$, $R(P) = V$. □

Exercise 102. Show for $T_n^{(m)}$, $\ker(T) = \{0\}$ iff T is one-to-one.

Proof. If $\ker(T) = \{0\}$, then for u, v satisfying $T(u) = T(v)$, we have $T(u-v) = T(u) - T(v) = 0 \implies u-v=0$, so $u=v$. On the other hand, if T is one-to-one, then since $T(0) = 0$, only 0 maps to image 0 under T , so the kernel of T must only contain 0 - then $\ker(T) = \{0\}$. □

Exercise 103. For $S_n^{(m)}, T_m^{(k)}$, show

1. $\ker(S) \subseteq \ker(T \circ S)$,
2. $R(T \circ S) \subseteq R(T)$.

Proof. -

1. $u \in \ker(S) \implies S(u) = 0 \implies (T \circ S)(u) \implies T(S(u)) = T(0) = 0 \implies u \in \ker(T \circ S) \implies \ker(S) \subseteq \ker(T \circ S)$.
2. $v \in R(T \circ S) \implies \exists u \text{ s.t } v = (T \circ S)(u) \implies v = T(S(u)) = T(w) \text{ for } w := S(u) \implies v \in R(T) \implies R(T \circ S) \subseteq R(T)$.
